Age: Anthropological Aspects

Paul Spencer, University of London, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Age-related problems (e.g., adolescence, mid-life crisis, or old age) have to be viewed in the context of the life course as a whole. The status of older people is bound up with the evolution of the family. In rural societies, the ambivalent regard for older people is especially associated with family tensions concerning rights in property, where the most senior members are the custodians of the land. Where there is no permanent property associated with the family, as among urban migrants or marginalized groups, there tends to be a loss of status associated with aging. The experience of aging is examined from a number of points of view: women have a different profile of experience from men; aging entails a discontinuous dialectical process whereby mounting contradictions within the family lead to critical changes, highlighted by rites of transition; the experience of aging has to be disentangled from the experience of historical change. In certain societies, age-set systems institutionalize the process of maturation and aging. The sheer complexity of these systems provide a unique opportunity to explore different facets of this process, notably in terms of tensions associated with the succession of generations within the family.

Age is a product of the process of aging, which is partly determined by the social environment. Recognition of this social component has led to various attempts to identify features of the life course historically, portraying them as unique to Western civilization. However, the ethnographic literature has revealed a considerable blurring of some of these stereotypes. Thus Philippe Aries' (1962) influential argument that 'childhood' as opposed to 'adulthood' is essentially a product of the industrial revolution may be challenged with reference to the widespread practice of initiation in other cultures, which frequently marks a transitional point in the life course, distinguishing distinct stages, and is associated with a range of beliefs associated with childhood and personal development (La Fontaine, 1985). Again, G. Stanley Hall (1904) is credited with 'discovering' adolescence as a further category that arose out of the industrial cities in America, leading to a developing interest in this topic; yet deviant subcultures associated with dispossessed youth have been noted in some traditional rural settings and extend even to studies of primate behavior (Spencer, 1965; Pereira and Fairbanks, 1993). Again, Leo Simmons' (1945) survey of the role of the aged in 'primitive' societies is often cited, suggesting that older people were highly respected as compared with the West, where the family has diminishing importance in the process of urbanization (Cowgill and Holmes, 1972). Yet the data for rural societies reveal a varied response to the problem of reconciling respect for the experience of older people with the frustrations arising from their overbearing power within the family and the liability of having to care for them.

The complexity of the problem has led to the development of more refined concepts among sociologists, focusing on particular stages of the life course as prime topics for investigation by specialized subdisciplines. In contrast to this, anthropological studies aim to be holistic, emphasizing that within a particular culture any role or status associated with age has to be viewed in the context of the life course as a whole. Thus, the marginalization of certain age categories – perhaps adolescence or old age – forms part of a wider pattern involving a complex of relations between young and old. Adolescent subcultures, for instance, may be viewed as an alternative to the authoritarian structure of the family, and a milieu where the more open-ended bonds between age peers sharpen their awareness of an alternative experience involving a more creative lifestyle, preparing them for future possibilities within the wider community. Again, some studies have indicated that stress and hardship during adulthood, perhaps a mid-life crisis, appears to reinforce people's ability to cope with the social discomforts of old age in due course. Conversely, a more cushioned life career appears to leave people more vulnerable to the sense of loss and isolation as they grow old.

The Family and Ambivalence toward Aging

Very broadly, ambivalent regard for old age is especially associated with the elaboration of the family as a corporate unit in preliterate agricultural societies. The evolution of the family, reaching a peak in such societies, is entwined with the evolution of age relations and the concept of 'Status' coined by Henry Maine (1861), where social position is ascribed by membership of a family. This is closely associated with power in the hands of the most senior members by age as the legitimate custodians of family tradition. In this milieu, cultural knowledge itself may be treated as a form of property, to be imparted or withheld. In a very pertinent sense, property relations within the family are age relations, creating powerful bonds and tensions (Foner, 1984). A common factor underlying the urban stereotypes of old age and adolescence is the demise of the family as a dominant institution (Maine's 'Status to Contract').

The premise of respect and even fear for older people is especially widespread in rural Africa, where it is often associated with strong patrilineal families and polygyny, which is higher in Africa than any other continent. This highlights the notion that children are the property of the family in 'Status-dominated' societies, giving the senior generation the power to marry off their daughters early and to delay the marriage of sons for perhaps a decade or more. So long as this regime can be maintained, extended bachelorhood facilitates widespread polygyny among older men. The array of life stages is illustrated in **Figure 1** with reference to the Samburu of Kenya, who

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12006-9

Figure 1 Age, status, and the demographic profile of a polygynous society (Samburu, 1960).

provide a clear-cut example, with no dispensation for younger men to marry early or for widows to remarry. The concave shape of the age distribution is characteristic of preliterate societies, where mortality rates are especially high among the young.

The figure also indicates the contrasting life trajectories of women who are married young to much older men. The depressed status of women in such societies has to be viewed in relation to their total life course. Whereas a boy tends to take the first step from the obscurity of childhood toward a promising adulthood with his initiation, the arranged marriage of a girl transforms her from the obscurity of childhood to an initially obscure role as a young wife with very restricted opportunities and a stranger in her new home. A view of women as the victims of male exploitation is particularly apt at this low point in their careers, and especially in societies where there is a sharp separation between male and female domains. An alternative viewpoint portrays women as active agents who can manipulate their depressed situation to their own advantage. This view becomes increasingly apt as a woman's life course develops and notably once she surmounts the restrictions of her reproductive years and is increasingly independent of her aging husband. In the prime of middle-age, the advantage still rests with men. However, this tends to be reversed beyond this point as men lose the will to assert themselves against younger more competitive successors and are edged to the margins of activity in community affairs. Women are less hampered by aging until they are too frail to play an active role. The process of growing old for women in these circumstances is to free themselves from the domestic routine, but not from their personal networks which focus on their growing family with a freedom to choose how they wish to involve themselves (Amoss and Harrell, 1981).

The Experience of Maturation and Aging

The experience of maturation and aging shapes the perception of time and hence its meaning in a quite fundamental sense. This may be analyzed in several ways. The first involves an autobiographical approach, viewing each major event of the life course as a unique experience that may form a pattern retrospectively, but can only be anticipated within limits. This merges into a view of history that is shared by a whole generation, and an analysis of this shared perception of aging has to be disentangled from history itself. Each generation has a different perspective, and hence a different view of historical change (Mannheim, 1952). Thus, when older people suggest that policemen are getting younger, this may be a sign that they are getting older; but when they suggest that bank managers are getting younger, this may accurately reflect a historically trend. Again, the excessive number of children in Figure 1 was presented in terms of a stable pyramid of aging and of power resting on a base that reflected a high child mortality. But the excessive number of children could also have anticipated a substantial increase in population, and this has been borne out by more recent censuses.

Correspondingly, the extent to which younger people are seen to subvert tradition may be an aspect of a continuous process of adaptation to new opportunities, and 'tradition' itself may shift as a new generation matures and takes over as its custodians. Or youthful subversion may be in part a response to their subordination – an adolescent rebellion that is mounted by each successive generation. In the absence of written records, only longitudinal studies, monitoring the process of change over a period of decades, can distinguish between irreversible historical trends and the tenacity of family structures, perpetuated by the recycling of vested interests and intergenerational strains. To the extent that a popular awareness of social change draws attention to recent innovations and gives an impression of the contemporary scene as a watershed between tradition and modernization, the persistence of age relations embedded in resilient family structures is less evident in short-term studies. Underpinning this resilience is the cumulative nature of privilege associated with age in 'Status-dominated' societies. Those who react against traditional restrictions in their youth become the new custodians as they age. Changes in fashion and outlooks may tell us as much

about rivalries between successive generations as about the long-term development of society.

A more interactive approach to the experience of aging, especially in tight-knit communities, focuses on the accommodation of major life transitions as a discontinuous process: a life crisis theory of aging. The significance of rites of transition is that they involve the wider community, even beyond the family, in a shared experience of irreversible change. In the space between these events or other critical episodes, people age physically, but the configuration of social relations remains unchanged and there is a sense of timelessness as trends leading to the next critical change unfold. When this occurs or is precipitated, the configuration of roles adjusts to a new status quo and in a sense everyone ages. There is a distinct step in time. In dialectical terms, there is a mounting contradiction between inflexible social relations and the unstoppable process of maturation and decay that undermines the array of power relations. From this point of view, the anxieties that accompany these transitions and shifting roles are also anxieties of aging. Critical life events and transitions are key points, both in the experience of aging for the individual and with regard to adaptation and regeneration within the community.

Age Systems and Hidden Knowledge

A third approach to the experience of aging has coined the analogy of a 'cultural clock' that prescribes the appropriate ages for major life transitions within any society, facilitating adjustment, and heightening the awareness of those who forestall or lag the norm (Neugarten, 1968; Souvain-Dugerdil et al., 2005). While this expresses an essentially conformist approach toward aging, it is a particularly appropriate model for societies with age systems. Because members of such societies are very aware of age, they provide an ideal type for examining a range of issues associated with the process of aging. In an age system, those of a similar age are grouped together as an *age-set* (or age group), maturing and aging together. Their position at any stage may be termed an *age grade*, consisting of an array of expectations and privileges. In effect, the age-set passes up an age ladder, rung by rung, through successive age grades in a defined progression, like children passing through school but over a more extensive period in a process that persists into old age. The left-hand side of **Figure 1** illustrates a society with such a system, indicating the extent to which the transitions from boyhood at initiation and to elderhood with marriage are closely associated with age. Each step in the demographic profile broadly represents an age-set, and the successive statuses for married elders could be elaborated to provide a more detailed set of age grades. In general, age-sets tend to involve males only, but they may also define critical aspects of men's relations with or through women, giving women a distinctive role within the age system. Thus, the position of a woman may be highlighted in relation to the age-set of her husband or father or sons, but women are only rarely grouped together by age, except sometimes during the brief period leading up to their marriages.

Age systems institutionalize the cultural premise of respect for age through a form of stratification that in effect inverts stratification by caste. In contrast with the *total immobility* of a caste system, where shared status is determined by birth and persists throughout life, age systems guarantee *total mobility*: a young man is initiated onto the lowest rung of the age ladder as a member of the most junior age-set, and is systematically promoted with his age-set from one age grade to the next toward the top. In stratified age systems, the hierarchy of age-sets is associated with *respect* for age, which younger people have to learn. The nuances of an age system relate to the process of promotion, involving certain pressures from below and resistance from above. It is these pressures, arising from the interplay between a concern for status and the physical process of aging, that provide the mainspring for the 'cultural clock,' which is normally perceived as a recurring cycle of promotions and delays, spanning the interval between successive age-sets.

Elaborate age systems are primarily associated with the pastoralist peoples of East Africa. The relevance of nomadic pastoralism appears to stem from the equality of opportunity in a setting where a mixture of acumen, commitment, and sheer luck determines the success of each stock-owner. Unequal fortunes tend to even out as the more successful convert their surplus into further wives as an investment for the herding enterprise, leading to larger families and the dispersal of this wealth among the sons of the next generation. Correspondingly, the ideals underpinning age-based systems are of equality among age peers associated with the ephemeral nature of wealth and fortune rather than the inheritance of privilege based on birth and accumulated capital. This is complemented by the premise of inequality up the age ladder, regardless of family or wealth, again endowing ultimate moral authority and ritual initiative on the senior age-sets. Age systems were more widespread historically, but have become outmoded by the gathering complexity and inequalities in the process of urbanization.

The position of older men as the repositors of tradition has an affinity with secret societies in West Africa and Papua New Guinea, where esoteric knowledge is acquired by stages individually and is only fully understood in later life by those that are eventually initiated into the higher levels of the organization. It is the hiding of these secrets rather than the elusive knowledge as such that displays power, impeding the progress *of individuals* up the career ladder toward the privileges at the top. Among East African societies with age systems, there is a similar mystique and hierarchy of power associated with age, where careers are controlled by the ritual authority ascribed to those higher up the ladder. However, it is as *age-sets rather than as individuals* that promotion takes place; and to the extent that the pace of promotions is controlled by older men, manipulating the 'cultural clock' to their own advantage, they are playing for time against the inevitability of their own aging. Older women, middle-aged, and even relatively young men may conspire in this, resisting the advancement of their juniors by age. For those that live long enough, the frailty of their aging does not diminish the awe for their great age.

The antithesis of the power of older men is the physical virility of youth, often associated with an alternative lifestyle in 'warrior societies.' This poses a contradiction between the moral advantage that lies with older men and the more

immediate interests of younger men, who may react against traditional restrictions. Historically, situations of political turbulence offered opportunities that favored youth, overriding the constraints of the age system. However, it is also characteristic of the periodic age cycle that certain phases may be associated with greater gerontocratic control over a new age-set. These are paradoxically aspects of the system where privilege is vested heavily in the hands of older men, notably over women and marriage, and this creates a certain power vacuum on the lower rungs of the age ladder, encouraging youthful rebellion. By viewing age systems as interactive enterprises concerned with the distribution of power with age, rather than in terms of 'gerontocracies' or 'warrior societies' as such, their apparent resistance to change relates to involvement in the system at all ages. Those who can claim certain privileges of youth also have a stake in their future as elders.

A holistic approach toward age systems leads one to examine the relationship between principles of age organization and aspects of the family. In polygynous societies generally, competition for wives can give rise to rivalry between brothers, and the delayed marriage of sons can precipitate tension between generations. Age systems can serve to diffuse these strains by imposing restrictions on younger men that bypass the family (Samburu), by creating an alternative and prized niche for younger men (Maasai, Nyakyusa), or by maintaining a disciplined queue toward marriage (Jie, Karimojong).

A clear link between age systems and family structures is illustrated by the extent to which recruitment to an age-set is often complicated by restrictions of generation: the position of the son within the system is determined in part by that of his father or birth order, giving rise to a hybrid 'age/generation' system, rather than one based solely on age (Stewart, 1977). The rules can be highly elaborate leading observers to speculate that these rules are either spurious or have been misunderstood. However, their implications for the distribution of power and authority with age are very specific, and understanding in each instance derives from a wider analysis of relations between old and young within the family and the wider community (Baxter and Almagor, 1978). Younger men have the advantage of physical virility and the rapid accumulation of practical experience. Age systems, and indeed any institutions that endow older people with power, may be viewed in terms of their ability to impose a moral superstructure with a higher authority. The claim of older people to be the true custodians of tradition, and often to have the closest rapport with the ancestors, places society above the brutish forces of nature and inverts the natural process of physical aging in a hidden display of power.

Urban Migration and the Changing Profile of Aging

Given the substantial differences between societies studied by social anthropologists, the patterns of aging in relation to family structure do not translate easily into general statements for rural society. Even Cowgill and Holmes suggestion that the breakdown of the family in urban settings leads to the neglect of older people does not allow for the development of networks and family businesses by astute migrants who maintain and even enhance their position as they age. Again, Maine's generalization concerning the evolution of law from Status to Contract does not allow for the hiatus experienced by rural immigrants seeking work in developing economies with rapidly growing populations.

This growth has precipitated a relentless movement toward expanding urban areas, where older people's control over indigenous knowledge and institutions associated with respect for their age are no longer relevant. Younger people are at the forefront of urban migration, generating growing urban families, and in time a growing sector of urban-born adolescents. With regard to Muslim countries, Huntington (1997: pp. 104, 118) has asserted that population growth 'and particularly the expansion of the 15–24-year-old age cohort, provides recruits for fundamentalism, terrorism, insurgency, and migration. Economic growth strengthens Asian governments, demographic growth threatens Muslim governments and non-Muslim societies.'

While Huntingdon's analysis may be pertinent to the development of Muslim societies, fanned by the divisive loyalties of fundamentalism, the problem of urban population growth is more general. Data for 30 Muslim countries outside sub-Saharan Africa revealed a median annual urban growth rate of 2.4% as compared with 2.0% for 85 other developing countries outside Africa (WDI, 2005). However, these figures are dwarfed by data recorded for 43 countries in sub-Saharan Africa which revealed a median annual urban growth rate of 3.6%. This implies a doubling of urban population every 35 years in the non-African non-Muslim countries, every 30 years in Muslim areas, and every 20 years in sub-Saharan Africa. The general problem of this phenomenon for a growing younger generation clearly has a wider relevance beyond Islam, and notably in sub-Saharan Africa. Generally, there is a massive problem of displacement, from the family on the one hand and from any wider social order on the other. Somewhere between Maine's 'Status' and 'Contract,' there is a void, a lawless anomie in a dispossessed struggle for survival. Clearly this has relevance for all ages among those caught up in this situation. However, it is the younger and most active generation that are best equipped to respond to the opportunities for subversion, creativity, and developing informal networks of trust as investments for an open-ended future. Beyond law, they are the vanguard. Official projections of the balance between youth and aging and growth vary wildly, because of the unreliability of the underlying assumptions. Changing demography by age and by scale will be the major challenge for democratic institutions. As the whole world is squeezed, the profile of aging will be affected in unpredictable ways.

Abstract

With the formation of the modern state and then the welfare state, a 'government by age' of the population has become widespread with, as a consequence, a multiplication of age policies. A few concrete examples of the application of age policies to childhood and old age show how they have institutionalized the life course and assigned functions and identities to the successive stages of life. This trend has, in turn, led to a generalization of age policies with comprehensive, coordinated programs for the old and young. The relevance and effectiveness of age policies are now under question. The advent of a postindustrial society corresponds to a deinstitutionalization and destandardization of the tripartite organization of the life course inherited from the industrial era. Age policies should no longer be the main tool of population management. They should be replaced with life-course policies that are better suited for achieving an 'age-integrated society.'

The formation of modern states has come along with a social and legal construction of the individual around, to a large degree, the universal, neutral criterion of age. What we call 'age policy' has arisen as governments have diversified and expanded their interventions for managing the population. A genuine 'government by age' has been set up; clear evidence of this being the operation of welfare states and their bureaucracies is described below. The implementation of age policies for childhood and old age serves as a concrete example of how these policies have developed into comprehensive, coordinated public policies in behalf of these age groups. Current studies insist, however, that using age as a major criterion in policy-making has perverse effects; it leads to the erection of age barriers and abets age-based discrimination. As a consequence, the relevance of age as a major instrument for state interventions has come under question.

Age Policy, a Product and Major Tool of Public Policies

The Expansion of 'Government by Age' with the Emergence of the Modern State

Along with the modern state has emerged a social and legal construction of the individual. At stake in this process is the creation of conditions that single out the individual for attaining autonomy from family and community bonds. The individual is thus considered "as the prime holder of rights and duties and as the prime target of bureaucratic and administrative acts" (Mayer and Schoepflin, 1989: p. 193). This construction is grounded on a set of universal age-based norms for marking the chronological continuum of life with significant thresholds and organizing it into successive stages.

The legal ages of majority, for voting or joining the army, for example, laid down the threshold for entry into adulthood and full citizenship. In like manner, as social legislation gradually regulated and then forbid child labor or set the age of compulsory schooling, it also defined the bounds of childhood while assigning it specific functions and roles. At the other end of the life course, pension systems and old age insurance funds have, by setting the age of eligibility for a retirement pension, signaled the end of adulthood and worklife, and laid the threshold for entry into old age, when people are to live on pensions without working – even though, given the longer life span, the association between economic inactivity and old age is coming unraveled.

Through these age policies, the state was able to perform its major duties: redistribute income between age groups or generations; maintain social order by assigning roles, statuses, activities, and identities to each age group and individual; and manage human resources throughout the life span. Owing to this government of the population 'by age,' the state distributed social activities, obligations, rights, and resources between the three stages of life: childhood, the worklife (adulthood), and old age. A literal 'age police' was instituted to borrow Percheron's phrase (1991), in which 'police' has the older meaning of government as an act of 'ruling.' This essential aspect of government actions has expanded along with the welfare state. As Smelser and Halpern (1978) have shown, the state oversees the organization of the school–family–work 'triangle.' The life course thus came to be organized in line with an orderly, hierarchical model of three successive, clearly delimited stages. Accordingly, the individual is either a child in school and dependent on the family (a stage of life related to policies targeting children, families, and education); or an adult who is employed and thus benefits, owing to his/her work, from coverage for various social risks; or a retiree eligible for a pension.

Each stage of life was associated with an activity endowing it with a meaning and identity distinct from the other two stages. Under this model, the individual's life revolved around work, which was associated with adulthood. Young people were educated to prepare them for work; and old age was the time for rest and retirement after a life of work. As welfare states arose and set age thresholds, this model was gradually institutionalized; it defined the rights and obligations specific to each stage of life.

Age Policy, the Main Tool for Shaping the Life Course and the Individual's Biography

Universal social entitlements under the welfare state have led to an individualization and periodization of biographies. These entitlements condition clearly distinct situations and have

widened the rift between the worklife and the periods before and after it:

> In the welfare state, the continuous flow of life is transformed into a series of situations all of which have a clear formal definition […] Periodization of life and proliferation of sharp transitions which derive from the social insurance system combine into a lifelong biographical pattern.
>
> Mayer and Schoepflin, 1989: p. 198

Owing to its rules based on the chronological age for receiving benefits, the welfare state standardized life events and gradually institutionalized the life course. All components of the life course were defined: the number of successive stages, their social contents, the timing for passing from one stage to the next, the nature (more or less ritualized) of these transitions, the milestones marking these thresholds, and, not to be forgotten, the forms of solidarity and competition between age groups or generations. This life-course institution conditions the individual's biographical itinerary, sets the timing, and determines his/her plans as a function of 'temporal horizons' (*see* Motivation: Life Course and Sociological Perspectives).

This tripartite life-course model underlaid the development of industrial society and its timing of events. As Castel (1995) has shown, 'industrial wage-earning societies' relied on a strong connection between the dependent economic status of wage earners and an extensive system (the welfare state) of protection against risks. We might add a third dimension to this analysis: this tripartite social organization of the life course placed work at the center of life and placed the individual in a long, foreseeable chronology. This temporality contrasts with what prevailed during the preindustrial era, when only the family (and not the individual) had a 'future,' and the passage from one age of life to the next was blurred and reversible (Hareven, 1986).

Implementing Age Policies: The Cases of Childhood and Old Age

From Policing Ages to Comprehensive, Coordinated Age Policies

Childhood, like old age, was not identified as such till the modern era. During the Middle Ages, it did not exist as an autonomous age of life. It emerged during the eighteenth century, when children were 'placed apart and reasoned' inside institutions that had the duty to educate them (Aries, 1962) (*see* Childhood and Adolescence: Developmental Assets). Likewise, the invention of old age owes much to retirement systems, which, by setting the eligibility age for a pension, have established a threshold and assigned old age the socially uniform meaning of 'pensioned inactivity' (Guillemard, 2000) (*see* Retirement and Encore Adulthood: The New Later Life Course). A wide range of age-based social legislation has been passed regarding these two age groups.

The first laws on childhood regulated child labor; but laws about schooling and the age of compulsory schooling would be the principal vectors of the institutionalization of childhood as a stage of life assigned to educating future citizens and workers. The development of welfare states with their laws on maternity leaves, child care, health care, and family allowances put the finishing touch on this social construction. Comprehensive, coordinated policies targeting childhood gradually took shape in developed countries. This widespread adoption of age-based programs immediately led to the specialization of the professions in charge of managing childhood. As childhood came to be identified as a specific stage of life, infant care, and pediatrics became specialties in the health professions (Heyns, 1988). As much can be said about the age-based segmentation of professions in social work such as professionals in nursery.

The invention of old age as a stage of life regulated by a specific policy occurred at the junction of two age policies: retirement and welfare measures that targeting the aged.

Old age gradually emerged with the generalization of retirement systems, which regulated the transition from the worklife to inactivity on a pension. These systems introduced chronological age as a formal eligibility requirement for putting an end to the worklife. They assigned an identity to this new stage of life whereas, till then, the patriarch endowed with the family's estate had nothing in common with the old people without any estate, who swelled the ranks of the destitute, the poor, the unfit for work, the disabled or handicapped (children as well as adults) who were to be taken in custody by poorhouses or to receive relief while living at home.

The invention and generalization of retirement pensions and old age insurance – definite examples of age policy – have played a decisive part in constructing and consolidating the 'tripartition' of the life course. Kohli (1987), pointing this out, has identified four processes in this social organization of the life course.

First of all, retirement systems have been a major factor in determining the order and ranking of the three stages of the life course – with work at the center as the meaningful activity during adulthood. This stage lies in between youth (devoted to education prior to work) and old age (associated with inactivity and a pension after work). These systems have staked out a life course where the individual's contribution during adulthood in the world of work conditions is the right to rest at the end of life.

Second, retirement systems, along with other social policies (such as education), have given weight to chronological criteria for marking the transition from one stage to the next (*see* Age Stratification). Age policies have thus helped 'chronologize' the life course, marked as it is by the legal ages for starting and leaving school (the latter separating childhood from adolescence) and for going on retirement with a full pension.

Third, this division of the life span into three stages marked by chronological milestones has standardized the life course. At the same age, nearly everyone predictably moves from one stage to the next. At an equivalent level of education, entering the world of work occurs at the same age for nearly everyone. And the retirement age sets the date when most people stop working. Long-term trends over the past 50 years in the age of withdrawal from the labor force provide evidence of this standardization. As pension systems expanded to cover more and more of the population, the average age for going on retirement gradually approached the age of entitlement to a full pension for wage earners (Kohli et al., 1991).

Fourth, pension systems have fostered the making of plans for the future. The individual no longer has the same prospects as in preindustrial society, when the family and private wealth determined the timing of the stages of life and individuals had

no future as such, since they died young. Only the family had a future. The development of old age insurance, along with the longer life expectancy, has led to an individualization and 'temporalization' of the life course. Pensions endow the individual with a future. As a consequence, retirement systems have furthered the change from a society of ascribed statuses (through membership in a family or local group) toward a society of achieved statuses and, thus, of mobility. In this new industrial society, the individual has personal plans. Thanks to old age insurance, security is now based on the person's worklife and/or citizenship rights – and no longer on his property, local bonds, or family status. To ensure this security, old age insurance relates successive generations through forms of reciprocity and statistical, long-term solidarity. It has thus contributed to erecting a new social order in line with the requirements of a society undergoing industrialization, a society of social mobility that exercises control over the future. This illustrates how the state's regulatory interventions instituted age-based norms for 'policing ages.'

As Graebner (1980) has shown in his history of retirement in the United States, the invention of the pension system was more than just a way to insure older workers who were no longer able to work. Companies used this system to control the flow of labor and develop human resource management in line with the principles of Taylorist Scientific Management. They thus rationalized the withdrawal of older workers from the labor force while replacing them with young people who were thought to be more efficient.

Once old age as a definite, foreseeable stage in the life course was instituted, welfare policies were gradually worked out for providing specific coverage to this age group. A range of welfare policies for the elderly provide services and facilities related to care and leisure.

In France, coherent public programs targeting youth and the elderly were drafted as of the 1960s. Their clear intent was to improve the management of these age groups and implement comprehensive and coordinated public action plans with integrated multilevel programs for responding to the specific problems of these groups. French public authorities published the first major report on old age titled – 'Old age policy' – in 1962. It contained a public action plan for integrating the elderly in society. In pursuit of this goal, home care was to be provided instead of institutional custody, which the report declared contrary to its objectives. As an analysis of French old age policy has shown (Guillemard, 2000), this report marked a turning point in diagnosing the problems related to old age. Fighting against poverty through interventions targeting income was now but one way, among others, of achieving social 'inclusion.' Since the main old age problem was said to be the lack of social integration, it was important to act on the environment and lifestyle of the aging population so as to help it – by building adapted housing, expanding home-care services or the neighborhood facilities necessary for helping them remain living at home – continue living an independent life as long as possible. These new policies focused on issues related to the way of life more than on improving living standards. A similar trend can be observed in the United States with the passage of the Older American Act in 1965 (Estes, 1979).

These old age policies emerged along with a segmentation by age of the professions responsible for managing this group, similar to what we have seen in the case of age policy for children. Geriatrics and gerontology became specialties in the health professions (Haber, 1986) and social work. Professional groups were formed around these new specialties, for instance the Gerontological Society in the United States and the Society of Gerontology and Geriatrics in France. They form what Estes (1979) has called 'the aging enterprise.' Later policies were drafted for caring for the frail elderly and the vulnerability of that phase of life, advanced old age (Olson, 1994).

The Perverse Effects of Age Policies

By implementing these age-based policies, public authorities invented and now regulate infancy, childhood, adolescence, old age, and advanced old age. They have assigned social contents and identities to these stages of life. These policies have not, however, always had the effects intended (*see* Population Aging: Economic and Social Consequences).

Research on the old age policies implemented in the United States or Europe since the late 1960s has shown that the measures for providing social services and facilities to help the aged continue living at home and avoid institutional custody (with 'marginalization' and lessened autonomy as consequences) have made these persons dependent (Guillemard, 1983; Walker, 1980). The central argument in studies on these perverse effects is that – despite both the good intentions underlying government interventions and the tangible results for beneficiaries – these programs have, in general, not maintained or developed the targeted group's autonomy. Arrangements for home services have, perversely, turned any physical, mental, or social disability into a form of 'dependence.' Thus emerged a new definition of the senior citizen as the "recipient of services whose extent and nature are decided by others" (Townsend, 1981: p. 19). Moreover, fragmentation in the provision of home-care has led to defining beneficiaries by a long list of needs for health care, social ties, home helpers, cleaning services, etc. A category of professionals has been assigned to satisfy each of these needs; and the beneficiary is the hub of a merry-go-round of services, as helpers, care providers, and professionals successively arrive at his/her bedside, according to their own schedules while the beneficiary lacks any control over the services thus dispensed.

The Rise and Fall of Age Policy

For more than a century now, the state has adopted an age-based management of the population. This form of management seems to have reached its limits.

In her pioneering book, Neugarten (1982) has questioned both the relevance of age as the main lever for handling the social problems of this age group and the efficiency of public policies targeting it. Her call for an 'age-neutral society' suggests organizing government interventions on the basis of needs instead of age. This questioning of the relevance of age is apparently related to current trends in developed societies. The advent of a postindustrial, knowledge-based, or network society (the terms varying according to the theorist) has upset industrial society's tripartite organization of the life course. The life course is becoming flexible (Best, 1981). Biographical itineraries no longer fit into the pattern of three distinct, successive, well-ordered stages. Continuity in careers is coming undone, as

periods of training and inactivity are interspersed throughout the worklife. The new imperative of lifelong learning undermines the idea of youth as a period specialized in education. The tripartite life course, its stages blurred, is being deinstitutionalized and destandardized (Guillemard, 2005).

The spread during the 1980s and 1990s of a wide variety of schemes for withdrawing early from the labor force is evidence of this deinstitutionalization (Guillemard and Van Gunsteren, 1991), since they subvert the regulated transition from work to retirement and wreak havoc in the orderly succession of the three stages of life. Although early exit, or preretirement, seems to signal an event that simply occurs sooner on the retirement calendar and nothing else of significance, these age-based measures have had so great an impact that we can interpret them as increasing flexibility at the end of a life course that is undergoing reorganization (Guillemard, 1997). The most frequently used early exit schemes were developed not under pension systems or old age insurance but instead under disability and unemployment insurance. In all countries, these extremely malleable schemes have continually evolved as a function of employment conditions. We can interpret this as a 'dechronologization' of the life course: the individual can no longer imagine a continuous, foreseeable life marked by chronological age thresholds.

The order of the stages of life and the activities assigned to them are no longer precise, and are even contingent. The timing of definitive exit from the labor market is unforeseeable. No one working in the private sector knows when (at what age) or how (under what conditions) they will definitively stop working. The chronological thresholds at the end of the worklife are no longer clearly visible. We now observe a leveling of age thresholds along with the reversibility of transitions and itineraries. These trends invalidate the relevance and effectiveness of an age-based management of the population, since, given the destandardization and individualization of biographical itineraries, individuals of the same chronological age might be living in very different situations. For example, a wage earner 50 years old might be experiencing late parenthood and still have children in school whereas another of the same age might be facing an 'empty nest,' the children having grown up and left home. The retirement strategies developed by these two persons will differ significantly. A single, standard retirement age cannot meet such different needs. Instead of an age-based management of the population, the destandardization of the life course calls for managing biographical itineraries. Life-course policies capable of providing 'flexisecurity' to individuals with destandardized itineraries must be designed to replace age policies (Guillemard, 2010). Riley et al. (1994) have drawn attention to the 'structural lag' between the expectations of the aging, owing to their long life expectancy, good health and extended capabilities, and the limited 'opportunity structures' offered by public age policies. She has drawn the conclusion that a new formula for combining work, family, and leisure must be worked out to create an 'age-integrated society' where work, family, and leisure activities are woven through all stages of life. This echoes the European Commission's call for a 'society for all ages' (EC, 1999), repeated in the "2012 European year for active ageing and solidarity between Generations" evinces the new interest in fighting against age barriers and age-based discrimination in employment (European Foundation, 1997) and in developing 'age-diversity management.'

Abstract

Age is a personal characteristic, a base of stratification, and a characteristic of populations. This article covers the sociology of aging at multiple levels of social organization. Topics reviewed include the age structures of populations, the challenges posed by aging populations, the distinction between aging processes and cohort differences, the effects of social change on cohort differentiation, and the relationships between age and individual well-being.

The sociology of aging is both broad and deep. The breadth of the field can be highlighted in several ways. First, the sociology of aging encompasses investigations of aging as a process of older adults as a group and of old age as a distinctive stage of the life course. Second, aging research is performed at multiple levels of analysis – from macro-level studies of age structure within and across societies, to meso-level studies of labor force participation and family structure, to micro-level investigations of health and well-being. Third, aging research uses the full repertoire of methods that characterize the discipline, including life tables and other demographic methods, survey research, ethnographic methods, and observational studies. The depth of the field results from the accumulation of scientific studies that now span more than three-quarters of a century.

Any attempt to summarize the state-of-the-science in the sociology of aging concisely will inevitably do justice to neither the breadth nor the depth of the field. Here, four major themes in theory and research on aging are reviewed. Selection of these themes is based on a review of appropriate reference works (e.g., handbooks and encyclopedias) and perusal of major journals and textbooks. Nonetheless, it is likely that other scholars would choose other themes, and those considered here are not exhaustive.

Age Structure and Its Implications

Although primarily the province of demographers, both scientific and public interest in aging partially rests on the aging populations characteristic of the modern world. Age structure is based on the sizes of age groups in a given society. In turn, the sizes of age groups are a function of fertility and mortality rates. The *theory of the demographic transition* provides a portrait of the relationships between development (i.e., industrialization, urbanization, and technological advances) and the age structures of societies (Bourgeois-Pichat, 1979). According to this theory, the demographic transition occurs in three stages. In the first, prior to and during the early years of modernization, both fertility and mortality rates are high. The result is an age structure that takes the form of a pyramid, with the largest age group consisting of children and older adults comprising the smallest group (*see* Age Structure). During the process of modernization (the second stage), mortality rates decline, but fertility rates remain high. The result is larger populations in total size and a young population. The dependency ratio, which is the proportion of the population in the labor market relative to the number of children and older adults not in the labor market, is high, but consists primarily of children. As societies achieve modernization (third stage), mortality rates continue to decline, but fertility declines as well. The theory of the demographic transition hypothesized that the third stage would lead to a steady-state population size, in which fertility and mortality rates would be approximately equal, and the age structure would take the form of a cylinder, with all age groups of approximately equal size, and the numerator of the dependency ratio including approximately equal numbers of children and older adults.

The first two stages of the theory of the demographic transition have been supported in empirical studies. Evidence for the hypothesized third stage is much weaker. Although both fertility and mortality rates have declined in modernized societies, fertility rates have declined faster than mortality rates, resulting in populations with disproportionately large numbers and percents of older adults. Two other demographic patterns have exacerbated the aging of the population in some societies. First, in the United States and, to a lesser extent, in Western Europe and Australia, the end of World War II ushered in a decade or more of unusually high fertility, resulting in a 'baby boom,' followed by the expected sizable declines in fertility (*see* Fertility Theory). These unusually large cohorts delayed the predicted declines in fertility, but because of the small cohorts that followed them, escalated the aging of the population. Second, countries in South America, Asia, and Africa have achieved substantial modernization with substantially smaller declines in fertility than expected. An exception to this pattern is China, where the 'one child' policy decreased fertility very rapidly.

The importance of the theory of the demographic transition is not in its accuracy, but rather in its attention to the age structures of societies and the effects of social change (in the form of fertility and mortality rates) on those age structures. Regardless of the indicator used (e.g., proportion of older adults and median age of the population), populations are aging rapidly in the United States, other western societies, and China.

Although initially slow to comprehend the significance of an aging population, both scientific and policy communities are now well aware of the challenges posed by an aging society.

'Young' populations also pose problems for societies, but solutions to those problems (e.g., child welfare and schooling) evolved gradually in modern societies and became institutionally embedded in custom and law. The aging of modern populations occurred more rapidly, resulting in significant structural lag (Riley and Riley, 1994) in institutional responses to the needs of older adults (*see* Population Aging: Economic and Social Consequences).

Demographic research has expanded substantially beyond questions of age structure per se. Most of what is now known about the prevalence, incidence, and course of disability is based on demographic research. Among the contributions of this research are findings that rates of disability among older adults have been gradually declined for approximately 20 years (i.e., in the 1980s and 1990s) and have now leveled off, that the higher rates of disability among women than men result from their greater longevity rather than higher incidence of disability onset, and that, although it is less common than the onset of disability, a sizable proportion of older adults recover or improve in functional status. The distinction between life expectancy (expected years of survival) and active life expectancy (expected years of disability-free survival) is also a high-priority issue. Interest in active life expectancy stems from the concern that the increased longevity characteristic of modern societies has been achieved by prolonging life after the onset of frailty and disability. Evidence suggests that the length of disability prior to death has not increased over the past several decades; however, there also has not been a decrease in the interval between the onset of disability and death. As these topics illustrate, demographers now devote a significant proportion of their efforts to understanding heterogeneity in the older population (*see* Retirement and Encore Adulthood: The New Later Life Course).

A large proportion of sociological research on aging rests on the challenges posed by an aging society, although that impetus is not always explicit. Studies of public and private transfers of money, time, and in-kind services rest in large part on their salience for sustaining an aging population. Studies of health, disability, and quality of life are important not only because they address threats to well-being, but also because they identify factors that keep older adults from excessive reliance on public programs. Even studies of the caregivers of impaired older adults rest not only on concern about the health risks of chronic stress, but also on the desire to enable families to bear as much of the cost of care as possible, thus relieving public programs. Thus, age structure and its social implications is a significant and far-reaching arm of aging research.

Aging as Context: The Significance of Cohorts

Multiple forces, both social and nonsocial, determine the process and experience of aging (*see* Aging, Theories of). Historically, there was a tendency to attribute the aging process and the experience of late life to inherent biological and developmental processes. Most of us are relatively ignorant of the extent to which the process and experience of aging vary across historical time, finding it difficult, for example, to imagine a time when there was no retirement or when the odds of dying were essentially the same during childhood, adulthood, and old age. And yet, retirement as a predictable life--course transition and odds favoring survival to old age both emerged in the twentieth century. The concept of cohort allows us to distinguish conceptually and empirically between inherent components of the aging process and patterns that result from social factors, especially social change and unique historical events or circumstances (*see* Period and Cohort Analysis in Demography).

Although cohort membership can be based on any event, the term is typically used for birth cohorts – for persons born at the same or approximately the same time. Cohorts share more than the timing of their births; they also experience the same historical events and social structures throughout their lives. Cohorts share collective experiences that often differ from those shared by earlier and later cohorts. Thus, there often are sizable cohort differences in the process and experience of old age.

Cohort differences, often observed across cohorts born in relative proximity, can be generated by multiple conditions. First, cohorts can differ substantially in size and composition. Substantial evidence documents that unusually large and unusually small cohorts differ substantially, especially in economic opportunities, with the latter more plentiful in smaller cohorts. Cohort composition can be affected by many factors including excess male mortality during wars, different birth rates across racial/ethnic groups, and changes in immigration policies.

Second, historical events can substantially alter the experiences of cohorts (*see* Life Course: Sociological Aspects). When many cohorts experience the same historical event, effects differ depending on age at the time of the event (e.g., wars most strongly affect young men). Even in the absence of dramatic events or dislocations, historical developments imprint cohorts differently, creating persisting differences (e.g., racial identity among African-Americans before and after the Civil Rights Movement). Substantial evidence suggests that historical events and social change generally affect adolescent and young adult cohorts more than they affect younger and older cohorts.

Third, social change creates cohort differences and the more rapidly the social change occurs, the greater the differentiation across cohorts. Social change, of course, takes many forms, ranging from changes in public policies (e.g., Social Security and Medicare created large cohort differences in economic status during later life), changes in the norms governing social behavior (e.g., norms concerning the acceptability of fertility outside of marriage), and major structural changes such as the shift from an industrial to a service economy. Technological change also generates cohort differences, with varying implications for the older population. For example, devices that save household labor or provide assistance in compensating for disabilities enhance the likelihood that older adults can live independently. Conversely, diffusion of technological changes often takes longer to reach older adults, distancing them from younger cohorts (e.g., personal computers and related use of the Internet).

Finally, older cohorts are inevitably affected by the composition of and changes occurring in younger cohorts. Responses to those changes can create related changes in older

cohorts. For example, the prevalence of custodial grandparents, although still small, increased dramatically over the past two or three decades. This change in older cohorts is a direct result of changes in fertility and childcare practices of younger cohorts.

Cohort comparisons comprise a substantial proportion of sociological research on aging. An issue that receives considerable attention is comparisons of the assets and liabilities that different cohorts bring to late life. To date, research findings paint a rosy picture of this form of cohort change. For more than half a century, successive cohorts have entered old age with higher levels of resources and fewer liabilities than the cohorts that preceded them. This pattern has been especially consistent for health, education, wealth, and the availability of social support, all of which are valuable assets in late life. Recent evidence suggests that this pattern will not continue indefinitely. With regard to health, for example, although early baby boomers are expected to live longer, on average, than their parents, they report higher prevalence of chronic illness and disability than their parents' generation did at the same age (Marin et al., 2009).

The large volume of cohort comparison studies is too large to detail here, but includes issues as diverse as political affiliation and voting behavior, family structure (primarily cohort differences in divorce, remarriage, and single-parent mothers), cognitive abilities, alcohol consumption, and rates of depression. Cohort comparisons also are important for policy planning and analysis. Comparison of cohorts before and after a major policy change, such as the enactment of Medicare, is one of the primary strategies used to evaluate the impact of broad-scale public policies. Cohort comparison studies also remind us that public policies targeted at older adults are not the only policies that create differential advantage or disadvantage across cohorts. Policies that enhance educational attainment during adolescence and young adulthood have long-term benefits, creating cohorts that are more advantaged as they enter old age than were older cohorts. The GI Bill, first made available to World War II veterans, for example, created dramatic increases in the educational attainment and economic resources with which those cohorts entered late life.

At the same time that cohort comparison studies have enjoyed success, a related body of research examines *intracohort variability*. Although there are often large differences across cohorts, cohorts are not homogeneous. Paralleling sociology more broadly, increased attention to heterogeneity has characterized aging research for the past five decades. Intracohort variability has received both conceptual and empirical attention. Two bodies of research have contributed most to this research base.

First, the attention paid to social location, as indexed by basic ascribed and achieved statuses, has increased dramatically. For decades, gender differences, racial/ethnic differences, marital status differences, and socioeconomic (SES) differences typically were examined perfunctorily, if at all. It was not until the mid- to late-1970s, for example, that women's retirement received empirical attention. There is now general consensus that age, race/ethnicity, gender, and SES represent basic social structural categories and are forms of social stratification. Investigation of these multiple forms of stratification has been incorporated in aging research and in the discipline more broadly.

Second, a compelling body of research demonstrates that historical events or conditions do not have uniform effects on cohort members. Some cohort subgroups are strongly affected by historical events; others are largely untouched by them. Several important studies demonstrated that the Great Depression had the strongest contemporaneous and long-term effects on late adolescents whose families experienced the greatest economic deprivation (Elder, 1999); that relatively few young adults participated in the political activism of the 1960s, but that there were persisting differences in the life patterns of those who did and did not (McAdam, 1990); and that veterans' emotional problems in middle and late life were largely a function of amount of combat exposure during World War II (MacLean and Elder, 2007). Broad-based cohort effects also have been observed for these and other historical events or conditions (e.g., the "children of the Great Depression" had greater concerns about financial security than earlier and later cohorts, regardless of the amount of deprivation experienced), but there is also great heterogeneity in the effects of historical events on cohort members (*see* Motivation: Life Course and Sociological Perspectives).

Intercohort comparisons and studies of intracohort variability are arguably the core of sociological aging research. These studies demonstrate that aging is not solely – or even primarily – a biological process, but rather that the aging process and the experience of late life are shaped by social and historical context.

Aging and Well-Being

The vast majority of aging research falls under the general topic of aging and well-being, with well-being broadly defined to include any social asset (e.g., economic resources and life satisfaction) (*see* Aging, Theories of). Social scientific interest in aging was spurred by concerns about the well-being of older adults in both absolute and relative (to other age groups) terms. This is probably not surprising. The history of sociology in general has been driven by concerns about social disadvantage – its prevalence, antecedents, and consequences.

The types of well-being examined in relation to aging are numerous. A partial list of the forms of well-being frequently studied in late life include longevity, physical health, disability, mental health, subjective well-being, economic status, and identity or sense of self.

Self-perceptions during late life is an important and understudied topic relative to studies of physical and mental health and subjective well-being. Two primary dimensions of self-perception are especially important: a sense of self-worth (typically measured as self-esteem or self-acceptance) and a sense of competence (usually measured as self-efficacy, mastery, or sense of control). These self-perceptions are important in their own right – most of us consider adequate self-esteem and sufficient self-efficacy essential components of well-being. In addition, these self-perceptions mediate many of the relationships between social factors and other forms of well-being, including physical and mental health and subjective well-being. For example, self-esteem has been shown to mediate the effects of education on health (Murrell et al., 2003) and of social stress on functional status (Forthofer and Janz,

2001). Self-efficacy mediates the relationship between physical activity and perceived quality of life (Phillips et al., 2013). Traditionally, sociologists tended to view self-perceptions as the province of psychology. There is now plentiful evidence, however, that the antecedents of these self-perceptions are primarily social – and that their distributions are concordant with multiple stratification systems. Adequate sociological explanations of variability in well-being will need to take these psychosocial processes into account.

Three major research strategies underlie most research on aging and well-being. First, some studies examine the well-being of older adults relative to that of younger age groups (e.g., Schieman et al., 2002; Siedlecki et al., 2014). Examples of this kind of research include age comparisons of rates of poverty, chronic physical illness, disability, mental illness, and levels of subjective well-being, self-esteem, and self-efficacy across age groups at a single point in time. These studies are of limited use in understanding the aging process because it is unclear whether differences across age groups are due to age per se or to cohort differences. But comparisons across age groups can be useful for both providing basic descriptive information about the relative status of older adults and for identifying issues important to public policy (e.g., whether it makes sense to target income-maintenance programs at specific age groups). That is, policy makers typically are more concerned about the unmet needs of older adults than they are about disentangling age and cohort effects.

A second strategy for understanding the effects of aging on well-being is to study adults longitudinally as they move from middle age to late life and from being young-old to being old–old (e.g., Lynch and George, 2002; Yang, 2007). The advantage of this strategy, of course, is that age-related changes in well-being are directly observed. These studies focus on the status of the elderly relative to earlier points in their lives, rather than relative to younger age groups. The limitation of these studies is that findings may be cohort-specific, rather than reflecting a consistent developmental pattern. In theory, sampling a large number of cohorts and studying them over long periods of time, investigators can determine whether patterns of change and stability are similar across cohorts. Unfortunately, few data sets are of sufficient breadth in both the number of cohorts studied and the number of measurements over time to permit conclusions about whether patterns of change and stability are generalizable or cohort-specific.

Patterns of change and stability in the multiple forms of well-being that have been studied to date cannot be detailed here. Importantly, however, there is no consistent pattern of age-related decline across all forms of well-being. Declines are the modal pattern for some forms of well-being, such as income and the prevalence and onset of chronic illnesses. Stability is the modal pattern for other types of well-being, including self-esteem and life satisfaction – at least until very late life (i.e., age 80 years and older).

A third strategy is to focus on variability within the older population; that is, to assess variability in well-being among older adults and to identify the antecedents of that variability. Either cross-sectional or longitudinal data can be used to study heterogeneity among older adults, but only longitudinal data permit investigators to establish temporal order between well-being and its presumed antecedents. Note that age is not the independent variable in studies of this type; instead, the independent variables are the presumed causes of variability in well-being.

Compared to studies of age structure and cohort comparisons, the theoretical underpinnings of studies of aging and well-being are typically richer and more complex. A broad range of theories is used in studies of well-being in late life. Most of these theories are imported in whole or in part from other domains of sociology. For example, stratification theories are used to examine both income dynamics and health inequalities in later life, stress theory is used in studies of physical and mental illness, network theory is used to understand older adults' patterns of social support, and aspiration and equity theories are used in studies of subjective well-being. In addition to importing theories from other domains of sociology, a substantial proportion of research on aging and well-being rests on theories developed to highlight the distinctive conditions of later life. Examples include activity theory, which posits that multiple forms of well-being are enhanced in late life by sustaining high levels of activity and engagement – and adding new forms of activity to compensate for losses that often accompany aging; the double-jeopardy hypothesis, which predicts that the combined statuses of being old and a member of a racial/ethnic minority have more damaging effects on health and well-being than their purely additive effects; and socio-emotional selectivity theory (Carstensen et al., 2011), which suggests that declines in social contacts in late life are a purposeful and effective strategy for sustaining high-quality relationships and high levels of subjective well-being. Clearly, the theories used to explain variations in well-being among older adults are rich and varied.

The independent variables used in studies of well-being during late life are typically measures of social status, social context, and social resources. Social context, as indexed by age, race, and gender, is related to economic well-being, physical and mental health, and longevity. As expected, traditional indicators of SES are significant predictors of longevity, physical and mental health, self-esteem and self-efficacy, and subjective well-being. Social resources, especially social integration (e.g., organizational and religious participation) and social support also have positive effects on longevity, health, sense of self, and subjective well-being. As this brief description illustrates, we know a lot about the factors that explain heterogeneity in well-being in later life (e.g., Forthofer and Janz, 2001; Murrell et al., 2003). These same social factors also explain much of the variability in well-being among young and middle-aged adults. As the body of research that compares predictors of well-being across age groups documents, the distinctive feature of well-being in late life is not the specific antecedents of well-being, but rather the distribution of those antecedents across historical and biographical time.

Aging as the Culmination of the Life Course

During the past 40 years, the life-course perspective has assumed increasing influence in sociological research, especially research on aging. The core of the life-course perspective is the proposition that lives unfold over time and that events and conditions at earlier phases of the life course have

persisting effects at later phases – either continuing direct effects or indirect effects via more temporally proximate events and conditions. Taking temporality seriously changes research questions and research methods in multiple ways (Elder et al., forthcoming; George, 2003). Most importantly, perhaps, long-term patterns of change and stability, often conceptualized as trajectories, are the primary focus of analysis. Investigators can study trajectories of independent variables (e.g., marital history), trajectories of dependent variables (e.g., patterns of recovery, remission, and chronicity in depressive symptoms) or both. In addition to the 'shape' of trajectories, duration in states of interest also may be important (e.g., length of time till recovery from disability).

Methodologically, life-course studies require either multiple measurements over long periods of time or retrospective data about earlier phases of the life course. Longitudinal data are more accurate than retrospective data, but most life-course investigators are willing to use retrospective data if they are all that is available. The statistical techniques most frequently used in life-course studies (e.g., latent growth curve analysis) are newer and more complex than those used in cross-sectional or short-term longitudinal studies. Other methodological problems, ranging from substantial attrition in sample size to difficulties in selecting measurement tools that are applicable across adulthood, emerge when using longitudinal data covering long periods of time. Nonetheless, it is the way that research questions are conceptualized that is the hallmark of life-course studies.

Life-course studies provide important information about trajectories of vulnerability and resilience. At their best, they also incorporate the processes by which early events and conditions have persisting effects on outcomes of interest measured decades later. Work by Elder and colleagues on the long-term effects of combat exposure provides a compelling illustration of the knowledge generated by life-course studies (MacLean and Elder, 2007). This research is based on the Terman men, a sample of unusually intelligent males tested on multiple occasions from childhood to early old age. Most of these men participated in World War II, although not all of them were exposed to combat – and among those who were in combat, amount of exposure varied widely. Elder and colleagues demonstrate that combat exposure is a significant predictor of physical and, especially, mental health problems 40 years later, controlling on other known predictors of physical and mental health in later life. They also identified the life-course achievements that allowed some of these combat veterans to avoid or minimize subsequent health problems. Men who achieved greater socioeconomic success, those who sustained contacts with other combat veterans, and especially those who had lasting, high-quality marriages were able to avoid or minimize the health risks posed by combat exposure. This research demonstrates the benefits of life-course research, documenting both the persisting effects of early trauma and the mechanisms that allowed some men to avoid those risks.

In aging research, the life-course perspective has been used most frequently to understand the effects of life-course patterns of SES on multiple forms of well-being in later life. The conceptual framework underpinning most of this research is the *theory of cumulative advantage/disadvantage*. This theory was developed nearly a half-century ago by Robert Merton, as a framework for understanding occupational success among college and university professors (Merton, 1957). Merton observed that, at job entry, assistant professors looked very similar on standard measures of productivity and occupational success, regardless of the status of the institutions in which they were employed. Over time, however, variability increased dramatically in levels of productivity and occupational success among professors, with those employed at resource-rich schools exhibiting patterns of increasing success and those at resource-poorer schools exhibiting steady declines in productivity. Merton referred to the pattern as the Matthew effect. Subsequently, it was and is referred to as cumulative advantage/disadvantage theory (Dannefer and Daub, 2009). In colloquial terms, the theory of cumulative advantage/disadvantage posits that "the rich get richer and the poor get poorer."

In general, what Merton observed among professors is true for SES over the adult life course. That is, SES differences are smallest during young adulthood and largest during late life (Palloni et al., 2009). This is true for income and SES differences are even more dramatic for wealth. Thus, cumulative advantage/disadvantage generates increasing economic heterogeneity over the adult life course.

The life-course perspective also has been valuable in accounting for health inequalities across the life course. As is true for income and wealth, SES differences in health are minimal during young adulthood. By middle age, however, there are large differences in health between the lowest and highest SES quartiles in the United States. Evidence is less clear during old age, with some investigators reporting that SES differences in health continue to widen during late life. Other researchers, however, report that SES differences in health are largest during middle-age and narrow somewhat during old age, although they remain significant (Brown et al., 2012; Dupre, 2007). At some point in late life, SES differences in health are likely to narrow as the result of selective mortality (i.e., the earlier deaths of many lower SES individuals). Some of the mechanisms that account for SES differences in health also have been identified. The benefits of education, occupational status, income, and wealth are, of course, much of the basis of SES differences in health. Other mechanisms that mediate the effects of SES on health include health behaviors; stress, including lifelong accumulation of stressors; and psychological resources such as self-esteem and mastery.

In addition to long-term trajectories of assets and liabilities, the life-course perspective also focuses attention on the persisting effects of early life events and conditions. For example, evidence demonstrates that parental SES predicts health during middle and late life, over and above the effects of individuals' own SES trajectories (Pavalko and Caputo, 2013). Indeed, limited evidence suggests that fetal growth *in utero* plays a substantial role in health during late life (Risnes et al., 2011). In addition to economic resources, lack of emotional support from parents during early childhood increases the risk of both depression and chronic physical illnesses in late life (Shaw et al., 2004). Similarly, a variety of childhood traumas – including child abuse, sexual abuse, persistent poverty, and parental divorce – are known to increase the risk of many mental illnesses decades later, even with other known risk factors taken into account (McLaughlin et al., 2011).

Although the volume of life-course research that extends to late life has increased dramatically during the past three decades, many other topics could be profitably addressed in a life-course framework. For example, although there is compelling evidence that social relationships are powerful predictors of health and well-being in late life, little is known about the relative importance of lifelong patterns of social bonds as compared to the effects of social networks developed in late life. Similarly, religious participation has been demonstrated to be a strong predictor of mortality and morbidity in late life (George et al., 2002). However, this research is based on studies in which *current* religious involvement is measured. Virtually nothing is known about how length of exposure to religious participation affects health. In other words, we don't know how long individuals must participate in religious activities before health benefits are observed.

The life-course perspective also renders the usual distinction between social selection and social causation moot. Studying the life course is the equivalent of studying patterns of selection and causation as they unfold across personal biography. And, of course, the effects of social causation observed earlier in the life course become selection effects for outcomes observed later in life.

The life-course perspective focuses on the complex links between social/historical change and personal biography. In addition, the life-course perspective is ideally suited to linking macro- and meso-level social conditions to individual behaviors and well-being, to tracing the effects of structural opportunities and constraints, highlighting the effects of human agency (i.e., personal choices) over the long haul, and documenting the many ways that the past is indeed prologue to the future. Thus, life-course research is an important and exciting part of the sociology of aging.

Abstract

Age stratification can refer to (1) the age composition of a population, (2) features of social structure, and (3) a 'conceptual framework' for approaching the study of age as a feature of societies as well as individuals. The age composition of the population is produced by the piling up of cohorts (those born during the same time period) at a single point in time, creating what has often been called an age pyramid – a diagram with age categories on the vertical axis and a sex-bifurcated population count on the horizontal axis. The relevance of age as a compositional feature of a population depends on the meaning and normative significance of age in social structure, which has varied substantially across time and across societies. At the same time, the social significance of age depends, to some extent, on the age composition of the population. In attempting to conceptualize the dynamics of age in terms of stratification, scholars have also analyzed the potentials of age as a basis for social solidarity and conflict, and have considered the relationship of age and other bases of stratification. The dynamics involved in these relationships often entail complex interactions between intracohort and intercohort patterns of inequality or other forms of differentiation.

In the human sciences, stratification generally refers to those forms of differentiation that entail ordinal ranking along a defined dimension. Age is an inherently ordinal phenomenon, anchored in the intersection of time and the event of birth. Those individuals born within a given time period comprise a cohort. The defining cohort feature of lived time, or age, defines age difference (Dannefer, 1988). Age strata, however defined, are thus comprised of the continuous succession of living cohorts, glimpsed at a single point in time.

Age Stratification as a Feature of Populations

Figure 1 depicts the age composition of the US population in 1900 and the projected pattern for 2040. The ranked difference is determined by different dates of birth, and succeeding cohorts are essentially piled on top of each other at a single point in time to form a 'snapshot' of the age composition of the population. A comparison of these two figures reflects the dramatic changes that occurred in the intervening 140 years, including population growth, increased life expectancy, recent fertility declines, and the shift of the societal burden of dependency away from youth and toward age. Such changes in age composition result from changes in fertility, mortality, and migration patterns, and have been significantly driven by the maturing baby-boom cohorts (b. 1946–64). Changes in these population processes have resulted from a diverse array of social forces as well as technological and public health improvements (Cutler and Miller, 2005; Anderson and Hussey, 2000).

Figure 1 US population in millions by 5-year age categories, 1900 and 2040 (projected). Source: US Census Bureau, 2012. Projections of the Population by Age and Sex for the United States: 2015 to 2060. Population Division, Washington, DC; Klein, H.S., 2004. A Population History of the United States. University Press, Cambridge (adapted).

The shape of the age distribution also has an independent impact on society more generally. Scholars of age recognize immediately the consequences of such shifts in age distribution of a population, which can affect aspects of society as diverse as employment prospects for graduating students, the meaning of old age, marriage markets, and one's economic life chances (Uhlenberg, 1992). Without some knowledge of social context, however, such figures reveal nothing about how age is implicated in the overall structure of society. The effects of age are always contingent on specific institutionalized regimes. For example, a shift in the aged dependency ratio might seem a very different kind of problem in modern welfare states than an agrarian economic system like in Nepal, where the family is expected to share the primary responsibility of providing a safety net for older adults, and where children and many elders may make valued contributions to the household economy. Thus, analysis of age strata inevitably requires a consideration of stratification as a component of social structure.

Age Stratification as a Feature of Social Structure

The Cultural Significance of Age

As a feature of social structure, the boundaries and character of age strata are anchored in the broader social meaning and definition of age and time. The social meaning of age depends upon the political, economic, and cultural significance of a given age stratum. The manner in which societies define age and cohort membership is, of course, not universal but variable. Indeed, the very awareness of age and cohort membership is variable and, ultimately, socially constituted as a more or less integral feature of the larger social order. Societies vary in how they count, in how they measure the passage of time, and in how they identify time of birth. In some societies, the age set – a group of individuals spanning several years – is the central social unit defining life stage and role transition processes (Foner and Kertzer, 1978). For instance, in an ancient Hindu tradition, age was considered meaningful only in relation to four life stages and role transitions (i.e., student stage, householder stage, hermit stage, and wandering ascetic stage) of an individual (Kakar, 1968). In many other traditional contexts, age is similarly defined in descriptive terms – perhaps referenced by memorable events, such as political transitions or natural disasters and without concern for chronometric precision. Indeed, the standardized measurement of both time and age are remarkably recent human practices, driven by economic and political developments (e.g., Baars and Visser, 2007; Bartky, 2007). Despite their widespread taken-for-grantedness, the modern practices of defining age and time by precisely quantified calibrations are thus not essential elements of human nature, but are recent products of historically and socially specific systems of language, ideas, and interests.

Age and Bureaucratic Rationality

Within a single society, the significance of age may undergo dramatic alteration in response to changes in other aspects of social structure. An obvious prototypical case is the transformation to modernity, which generally meant the emergence of age-graded strata supported by newly identified life stages, the legal-bureaucratic reliance on age as an eligibility criterion, and an increase in age consciousness (Chudacoff, 1989). The result has been the institutionalization of the life course (Kohli, 2007). Viewed as a contemporaneous societal cross-section, this same phenomenon comprises the institutionalization of age strata in which the everyday experience of members of the several age strata are differentially organized by legal, governmental, and corporate policies and broader social practices that are explicitly age graded. In age-graded societies, such as modern welfare states, the stratum membership is a quite robust basis for predicting one's likelihood of being socially engaged or 'significant' (Uhlenberg, 1988).

Standard sociological wisdom declares that modern states assign roles based on universalistic criteria that reflect individual abilities rather than sponsorship or ascription. It is thus ironic that these societies have developed criteria (both formal and informal) to govern access to and exclusion from valued social positions based on the ascribed characteristic of age. 'Children,' 'adolescents,' and 'retirees' are examples of life-stage constructs that authoritatively define 'natural' capabilities based on age, even though these 'life stages' were largely unheard of before 1850s. As was true in many other agrarian societies, in the preindustrial USA it was not age but physical functioning and social status (e.g., owning land) that determined one's social position (Chudacoff, 1989; Demos, 1978). The same appears to have been the case in ancient times (Parkin, 1998).

Age has proven to be a useful criterion for bureaucracies faced with the task of managing and processing large populations. It has been used to regulate access to scarce roles and resources, and for attributing competence (or its lack) to individuals based on generalized assumptions of age-related capacities rather than actual abilities. Such practices are taken for granted, in that the rationality of age as an exclusionary criterion is seldom questioned by the rational-bureaucratic logic of the systems that rely upon it, just as ageism a social bias, often goes unrecognized by the most passionate activists for social justice in other areas.

Age Stratification and Social Theory

The Age Stratification Paradigm

The organization of society in terms of an age-stratified social structure must be analytically distinguished from the composition of the population of individuals of different ages who occupy positions in the social structure, and who move through a sequence of age-graded roles as they age. This fundamental sociological distinction between actors and structure, and persons and roles, was articulated for gerontology by Matilda Riley and associates four decades ago, but is still often overlooked (Dannefer et al., 2005; Riley et al., 1972). Confusion can arise if this analytical distinction is not recognized (e.g., when normative age-graded roles become taken for granted and assumed to be part of human nature). The importance of this distinction is a key premise of the pioneering age stratification – later termed 'aging and society' framework – advanced by Matilda Riley and associates (Riley et al., 1972).

One key principle of the aging and society framework is *structural lag* – 'society's failure to provide meaningful roles …,'

for people of all ages (Riley et al., 1994). The archetypal example is the incongruity between (a) a dramatic growth in longevity and late-life vitality among aged individuals and (b) social institutions and policies that are premised on entrenched ageist beliefs in the incompetence and obsolescence of the aged. Riley's work thus provided a sociological foundation that supported or anticipated other scholarly and popular efforts to question the prevailing social organization of age roles.

Some have criticized Riley's approach for its reliance on terminology associated with functionalism. In fact, her approach posed a challenge to the traditional functionalist position, by making visible the human costs and contradictions of age-graded social structures, with the intent of challenging conventional views that prevailed within as well as beyond the social sciences. It is only by making clear, for example, that men and women are not naturally *supposed* to engage in a 40-year stint of uninterrupted work, or that older people must not *inevitably* 'retire,' that it becomes possible to have a basis for a critical analysis of the social organization of age. Allocation implies the existence of an age-stratified opportunity structure with a finite number of roles, within which individuals must find meaningful social engagement. Given the limited elasticity in the number of available age-graded roles, there is considerable potential for an 'imbalance between persons and roles' which can mean an exclusion from desired social participation that is costly for both the individual and the society. Since the cohorts that populate strata are constantly aging, this is especially true when there are sharp discontinuities in the size of adjacent strata (or changes in the aspiration or abilities of stratum members). In stratification terms, such a situation may be called a disordered age structure, a cross-sectional 'snapshot' perspective on Waring's (1975) important concept of disordered cohort flow.

More generally, an issue of ongoing debate in this area concerns the question of whether the potentials of individuals can be realized within an institutionalized role structure imposed by governmental and corporate practices and the resultant norms that regulate access to roles on the basis of age. The systems that produce allocation problems also legitimate and sustain normative age-related expectations, especially those associated with the linear life course consisting of the 'three boxes' – of school, work, and retirement. As a structural alternative to this model, Riley and Riley (1994) proposed a model of an 'integrated life course,' which would imply a dismantling, or as Held (1986) has termed it, "deinstitutionalization" of the life course.

Thus, the terms 'age-integrated life course' and 'deinstitutionalized life course' both envision a similar process and direction of social change. However, the manner in which this process is framed can appear quite differently. On one hand, the idea of an integrated life course within which work, schooling, and leisure time can be experienced in balanced proportions throughout the life course, offering individuals a wider range of life options and opportunities. In this model, control of the design of the individual life-course shifts away from an institutional regime that has tended to stratify individual opportunities and normative possibilities according to age stratum boundaries, and toward an arrangement that affords a greater voice for self-expression.

At the same time, many postindustrial societies with advanced forms of life-course institutionalization (including elaborate education, welfare, and pension benefits) are facing the reality of challenges and in some cases erosion of the institutionalized life course, driven by the daunting economic and demographic challenges, and visible in the midlife disruption of careers once thought to be secure, or in high unemployment rates of young adults, or reduced pension benefits. Such changes may prompt wistfulness for the security of the institutionalized life course, despite ambivalence toward its oppressive aspects.

As examples of other social-structural approaches to age, two general lines of theorizing will be briefly discussed: (1) the effects of cohort size and composition and (2) the potentials for intergenerational conflict.

Effects of Stratum Size

Several scholars have argued that cohort size (and hence, stratum size) has a range of consequences for the lives of cohort or stratum members, including psychological (Waring, 1975) and socioeconomic (Easterlin, 1987) effects. The general argument is that large cohorts are disadvantaged relative to smaller ones, since their members must compete for scarce, age-graded roles and resources. Such ideas have found support in analyses of education and work careers based on aggregated data (Pampel and Peters, 1995; Dannefer, 1988). Of course, all such notions rest on the premise of a rigidly stratified age-role structure: of age as a normative if not legal qualification for occupying desirable educational and occupational positions. To the extent that this is true, the movement of unusually large cohorts through the age structure should mean that the status and resources of the various strata will change over time as the size of strata changes.

The rapid demographic change of the past century has provided a natural laboratory for exploring hypotheses about the relation of the age structure of the population and individual lives.

As increasing life expectancy has produced a graying of the population, elders may also experience disadvantage based on their numbers. For example, in preindustrial USA, the very old were often seen as the experts regarding health and longevity (cf Achenbaum, 1979). They were few, and with no prestigious medical profession, many of these survivors carried a mystique that seemed to imply expertise. Nevertheless, as will be shown in subsequent sections, the status of the aged in nineteenth century USA as in other premodern societies derived from much more than the rarity of nonagenarians. It was broadly rooted in the control of resources by the aged, and the limited options open to young people – circumstances fixed by laws of inheritance and other customary practices that organized the distribution of power in society.

Interstratum Inequality: the Intersection of Age and Other Bases of Stratification

As an ordinally ranked characteristic, age itself is an analytically distinguishable basis of stratification. Yet its significance typically involves its intersection with other dimensions of stratification, especially those involving control of economic, political, or cultural resources, demarcating differentiation or stratification *within* a given age stratum. However, the

interpretation of interstratum differences becomes a central concern. Differences in any measurable characteristic (e.g., health, wealth, and political attitudes; intrastratum inequality) may represent life-course, cohort, or period effects (Yang, 2008; Riley et al., 1972; Dannefer, 1988). In a cross-cultural analysis of age inequality and conflict, Nancy Foner (1984) identified several factors that privilege senior age strata in many societies: control over human and material resources; knowledge, expertise, and experience; prestige and status; community influence; and wisdom or mystical power. Many of these factors also appeared to operate in preindustrial Western societies. With the transformation to modernity, the aged lost both status and economic power, as the venerated characteristics of experience, skill, and wisdom were supplanted by physical strength and endurance, youthful beauty, up-to-date knowledge, and willingness to deal with rapid change.

Some scholars have argued that this structural transformation brought relief to strong intergenerational tensions that were present in many traditional agrarian families in New England and in Europe as, for example, when senior landholders survived until their children were well into or past middle age. When the family was replaced by the firm as the primary unit of economic production, the central familial relationship of economic dependency was removed (Kertzer and Laslett, 1995) – meaning that the relations of adult children and aging parents became more premised on volition and sentiment, rather than economic interests. By contrast, others have proposed that the rapid pace of technological and educational change characterizing modernity tended to create cleavages between cohorts in worldview and values, dramatically increasing the likelihood of interstratum conflict.

In either case, the characterization of modernity as removing the issue of intergenerational economic strain places the entire topic of the prospect of interstratum conflict on subjective grounds. Both arguments focus on values and sentiments. Nevertheless, a resurgence of arguments about economic interest as a source of interstratum conflict occurred in the late twentieth century as concern over the cost of entitlements for the age became a widespread public concern in most modern and postindustrial societies.

Economics and Generational Equity

In the USA, the politicized generational equity controversy has in various guises persisted since the early 1980s. This debate returns economic issues to the foreground of potential age conflict, and illustrates the potential for age to become a basis of interest-group politics (Williamson et al., 1999). The debate is fueled by opposition to the scale of age-based 'entitlements' and by discontent over what is seen as dramatic shifts in the age distribution of resources, especially from children to old people. Even though it can readily be argued that the age-qualified pensions and transfer payments given to older adults have also indirectly benefited younger adults, the proponents of generational equity controversy only highlight special economic consideration in such policies to the senior age strata (Schulz and Binstock, 2008). If being in a large cohort/stratum is disadvantageous for educational and employment opportunities, it may be the reverse for interest group politics, where the senior strata are recognized as comprising an active and growing segment of the electorate.

Grounded in such worldview, the USA continues to see vigorous efforts to pit young versus old (Peterson, 1999). Yet such efforts have yet to gain significant political traction. This failure was essentially predicted by theoretical principles set forth by Anne Foner. One such principle, *age mobility*, sees the inevitability of aging as producing anticipation on the part of midlife adults of their own certain movement into more senior age strata (Foner, 1974). A second principle involves the insulation from direct responsibility for dependent parents that Social Security and Medicare/Medicaid provide to adult offspring. Although intergenerational resource transfers may be more likely to go from parents to children than the reverse, the protection that many midlife adults are afforded by public subsidy of seniors is very real. Indeed, 'downward' resource transfers may depend, in many cases, on the public benefits afforded to the senior generations (Albertini et al., 2007). Other sources of resistance to 'generational equity' may include a belief in intergenerational economic continuity within families, which implies a relatively stable intergenerational reproduction of the structure of economic inequality along familial lines. For example, it may be the affluent neighbors or overpaid supervisor who become the focus of a sense of economic deprivation and limited life chances, and not one's comfortably situated parents.

Interstratum Variation in Intrastratum Inequality

Awareness of nonaged-related economic inequalities that are based on stratification of the general opportunity structures is made even more likely since intrastratum economic disparities appear to be greater in aged strata than in younger ones, as economic inequalities appear to cumulate across the life course of each succeeding cohort (Dannefer, 2003, 1988), creating a picture of an age structure in which inequality in a wide range of outcomes (e.g., socioeconomic status and health) is higher in the older age strata than in younger ones.

Despite characterizations of many traditional societies in gerontocratic terms, it appears that many aged in such societies enjoyed neither wealth nor status. Evidence for this comes from studies of the preindustrial USA (e.g., Demos, 1978) as well as from traditional (Foner, 1984) and ancient (Parkin, 1998) societies. If elders were often the most powerful members of traditional societies, it does not follow that most members of those age strata were affluent or particularly respected. Overemphasis on within-stratum homogeneity and between- or interstratum differences has often come at the cost of not exploring within-group differences or intrastratum inequality. Just as intercohort differences in patterns of intracohort inequality has been a neglected area of life-course research, interstratum differences in intrastratum inequality is a neglected question in analyses of age structure.

Summary

Age stratification brings together the deceptively elusive individual characteristic of age, and the complex and dynamic social phenomena of age as a social construct and as a basis of

stratification. A grasp of society as a systemic structural reality that shapes many aspects of aging has been slow to develop among those who focus on the individual-level characteristics of age and development. Conversely, a grasp that individual social actors – whether citizens, students, parents, or workers – are arrayed in continuously aging and changing cohorts has been underappreciated by sociologists. The study of age stratification has contributed a clear and forceful message concerning the importance of distinguishing age and age-specific subpopulations on the one hand from normatively age-graded social practices and structures on the other. It has contributed principles helpful in understanding how population and social structure jointly impact individual life chances, and has begun to consider the conditions governing the form of the relation of age and other bases of stratification. As issues such as the impact upon individuals of age-graded structures and the question of how socioeconomic stratification and age may interact, new research agendas have begun to take shape around questions of stratification and age.

Age Structure

Abstract

Trends in the age structure of a population should be considered in policy development and planning by governments and private businesses, because demands for goods and services, labor force participation rates, health conditions, and people's behavioral patterns vary substantially with age. Age structure is primarily determined by fertility, mortality, and migration during the last several decades. Most developed and developing countries in the world have experienced notable changes in the age structure due to significant declines in fertility and mortality. Various statistical and mathematical tools have been developed for measuring and analyzing age structure trends and their effects.

The age structure (or age composition) of a population is the pattern of its distribution by age. The age distribution is often shown separately by sex and displayed as the *population pyramid*, in which the sizes of age–sex groups are indicated by horizontal bars arranged from the youngest age-group at the bottom to the oldest age-group at the top. Several examples of population pyramid are in **Figure 1**. The graphs are called population *pyramids* because the graphs often exhibit triangular shapes, partly due to the tendency for the number of survivors to decrease with age and partly due to the increasing size of birth cohort in growing populations. The age structure is *young* if the proportion of younger people is high and that of older people is low (e.g., India, 1980, in **Figure 1(c)**). The age structure is considered *old* if the opposite is true (e.g., Sweden, 2011, in **Figure 1(b)**).

It is crucial to consider current and prospective changes in the age structure when planning government policies and forecasting consumer demand and labor supply for private industries (*see* Age Policy; Population Aging: Economic and Social Consequences). Demands for different types of goods and services vary significantly with age. A large youth population implies high demand for school facilities and teachers. A greater elderly population may mean more needs for nursing homes, medical services, and hospital facilities and a higher amount of pension payments. A society with a rapidly increasing number of people in 20s and early 30s may need to create more employment opportunities and provide new housing.

Furthermore, labor force participation is null or low at both the ends of age spectrum and high in between. If the proportion of the working-age population (between the age when people typically start their first full-time job and the typical retirement age) is decreasing, people in the labor force may have a growing burden of economically supporting those outside it.

Underlying these societal consequences of age structure are age variations in health conditions, behavioral patterns, and socioeconomic characteristics of people (*see* Motivation: Life Course and Sociological Perspectives; Life Course: Sociological Aspects). This is partly because humans experience substantial age-associated physiological changes in their lives (physical development at young ages, sexual maturation, and senescent processes at middle and old ages), and partly because age-related social roles have been built on these biological life history patterns.

Population Dynamics and Age Structure

The age structure is determined primarily by the levels, age patterns, and trends of fertility, mortality, and migration during the past few decades (Coale, 1972). A population with higher fertility tends to have a larger proportion of children, and a population with lower mortality has a higher proportion of people who survive to old ages. In a growing population, the sizes of more recent birth cohorts tend to be larger, producing a young age structure, but a decreasing population tends to have an old age structure.

The migration rate tends to be high among young adults. Thus, usually migration reduces the proportion of young adults in countries that send out migrants, and increases the proportion in countries that receive them. The long-term effects of migration on the age structure are complicated if fertility and mortality patterns of the migrants are considerably different from those of the native population, or if there are significant flows of return migration.

During the last one and a half centuries, the age structure has become older in the majority of countries in the world. Significant population aging started during the first half of the twentieth century in most economically and technologically developed countries, and it started during the second half in many developing countries. Figures 1(a) and 1(b) illustrate the historical age structure changes in Sweden, indicating that the age composition of Sweden is noticeably older in 2011 than in 1900. Figures 1(c) and 1(d) show data from India as an example of a developing country. The relative narrowing of the pyramid base from 1980 to 2011 reflects recent fertility declines in India. The difference in the timing of population aging between developed and developing countries is illustrated in **Figure 2** for Sweden and India.

The population aging was due to considerable declines in mortality and fertility. This international demographic trend is called the *demographic transition*, which accompanied the industrialization of economy and related social changes. The age structure of developed countries, where the demographic

transition started earlier, is significantly older than that of developing countries. (For example, compare the population pyramids of Sweden, 2011, in **Figure 1(b)**, and India, 2011, in **Figure 1(d)**.)

Until recently, the major driving force of age structure changes in the demographic transition was fertility declines (Coale, 1972) (*see* Fertility Theory). Although the significant mortality decline started before the significant fertility decline in the majority of countries, the age structure of some populations became younger in early phases of mortality decline, as the pronounced reduction of infant and child mortality increased the number of young children. The decline in the

Figure 2 Trends in the median age of population for India, 1950–2010 (thick line) and Sweden, 1751–2011 (thin line).
Source: India: United Nations (2012). World Population Prospects: The 2012 Revision; Sweden: *Human Mortality Database*. University of California, Berkeley (USA), and Max Planck Institute for Demographic Research (Germany). Available at http://www.mortality.org (data downloaded on 02.04.14.)

median age of India's population in the 1950s and 1960s, seen in Figure 2, may be due to the decrease in youth mortality. However, during the last few decades, reductions of old-age mortality in many developed countries had strong impacts on population aging (Horiuchi, 1991; Preston et al., 1989; Preston and Stokes, 2012; Vaupel and Jeune, 1995).

The age structure may also show significant fluctuations in cohort size, reflecting temporary changes in fertility, mortality, or migration. Events such as famine, drought, epidemic, and war often reduce fertility and disproportionately increase death rates for infants and young children, producing relatively small cohorts who were born during or immediately before the catastrophic period. Wars may also cause considerable attrition of cohorts deeply involved in combat. Figure 1(e) shows the population pyramid for West Germany, 1960, in which the proportions aged 40–44 and 10–14, born during the World Wars I and II, are substantially small. Also the male cohorts aged 35–54 were noticeably smaller than their female counterparts, reflecting gender differences in mortality of young adults during World War II.

Temporary rises in fertility (baby booms) also produce significant cohort size variations. In Figure 1(f), the relatively high proportion of population aged 25–44 in the United States, 1990, is due to the baby boom after World War II. Such cohort size variations may be echoed among later cohorts. For example, Figure 1(f) shows that under 15 years of age, the size of younger cohort is larger, probably because cohort size variations among the baby boom cohorts were repeated by those among their children, though with some diminution.

Measurement of Age Structure

Age structure can be considered as a pattern of C_is, where C_i is the proportion of the population that falls in age-group $i(i = 1, 2, \ldots, n$ and $\sum_{i=1}^{n} C_i = 1)$. With age as a continuous variable x, age distribution can also be represented as the density function $c(x)$ for the proportional distribution of population by age. Then the proportion of population that falls in the age interval between a and b is expressed as $\int_a^b c(x)\mathrm{d}x$, and $\int_0^\infty c(x)\mathrm{d}x = 1$.

Table 1 Estimated summary indicators[a] of age structure for selected countries[b], 2010

	Median age	*C(0–19)*	*C(65+)*	*Age-dependency ratio*
Kenya	18.5	53.1	2.6	125.7
India	25.5	39.9	5.1	81.8
Brazil	29.0	33.9	6.9	68.9
Sweden	40.7	23.4	18.2	71.2
Japan	44.9	18.0	23.0	69.5

[a]C(0–19) is the proportion (in %) of population aged under 20 and C(65+) is the proportion of population aged 20 and over.
[b]Countries are listed in the ascending order of median age.
Source: United Nations (2012). World Population Prospects: The 2012 Revision.

Common summary measures of age structure include the mean age of population, median age of population, proportion of population at young ages (e.g., under age 20), and proportion of population at old ages (e.g., age 65 and above). The age-dependency ratio is the ratio of the population outside the working-age range to the population in the age range. The working-age range is defined as ages between x_1 and x_2 (usually including x_1 but excluding x_2), where x_1 is a typical age at the start of the first full-time employment and x_2 is the typical age of retirement. Since multiples of 5 are preferred, 15 and 20 are widely used for x_1 and 60 or 65 for x_2. The ratio is usually multiplied by 100. It is used as a measure of effects of the age structure on the extent to which people in labor force have to economically support those outside labor force. Also used are the child-dependency ratio, which is the ratio of the population under x_1 to the population between x_1 and x_2, and the old-age dependency ratio, which is the ratio of the population aged x_2 and above to the population between x_1 and x_2 (for a more detailed explanation of measures of age structure, see Hobbs, 2004).

Table 1 shows the median age of a population, proportion under age 20, proportion aged 65 and over, and age-dependency ratio (using 20–64 as the working age) for five selected countries that have different age structures. Kenya has the youngest age distribution among the three developing countries, followed by India and Brazil. The differential age structures of the three countries reflect different timings of their demographic transitions. As for the two developed countries, Sweden started its demographic transition much earlier than Japan, but now the age structure of Japan is older than that of Sweden, because of the steep declines in fertility and mortality in Japan during the last few decades. The age-dependency ratios of Brazil, Sweden, and Japan are fairly close, indicating that populations with different age structures could have similar age-dependency ratios, if the sum of the proportion under the working-age range and proportion above it happen to be close among those countries. Overall, Table 1 suggests that currently there are very large variations in age structure among countries in the world.

The direction and pattern of age structure changes in a population are indicated by the profile of age-specific

Figure 3 Annual rate of population growth by age for Japan, 2010. Population size estimates by 5-year age-groups were used, and geometric rates of change in percent were computed. The dashed line indicates the growth rate of total population. Source: Human Mortality Database. University of California, Berkeley (USA), and Max Planck Institute for Demographic Research (Germany). Available at http://www.mortality.org (data downloaded on 02.04.14.).

growth rates for the population (Horiuchi and Preston, 1988). For example, **Figure 3** shows that although the total population size of Japan remained nearly constant during 2010, the population under age 30 decreased and the population aged 55 and over increased. In particular, the population aged 95 and over grew by about 15% in the year. The proportions of age-groups with higher growth rates than that of the total population increase, and those of age-groups with lower growth rates decrease. Thus, the large age variations of population growth in **Figure 3** suggest that the age structure of the population of Japan was changing fairly rapidly in 2010.

It should be noted that some demographic data on age must be used with caution because self-reported ages in populations with low literacy rates may not be accurate (Hobbs, 2004). Particular attention should be given to ages of old persons and old decedents in historical demographic data collected in those days and data from current developing countries, partly because older cohorts tend to have higher illiteracy rates in many countries, and partly because age inaccuracy tends to produce larger biases in statistics on older adults (Preston et al., 1996).

Age-Standardization

The incidence of various events (such as marriage, childbearing, and death) is strongly associated with age. The crude rate of such an event, usually computed as the ratio of the number of the events in a year to the total midyear population, could be significantly affected by the age structure of the population. Thus, for comparing the rate among populations, it should be adjusted for age structure differences.

For example, the crude death rate (CDR) is the ratio of the number of deaths in a year to the total midyear population, usually multiplied by 1000. CDR is strongly affected by age structure, because it is the sum of age-specific death rates weighted by the proportion of the population in that age-group:

$$\mathrm{CDR} = \frac{D}{N} = \sum_{i=1}^{n} \frac{D_i}{N_i} \cdot \frac{N_i}{N} = \sum_{i=1}^{n} M_i C_i \qquad [1]$$

where D is the total number of deaths in the year, N is the midyear total population, n is the number of age-groups, D_i is the number of deaths in age-group i, N_i is the population of age-group i, M_i is the death rate of age-group i, and C_i is the proportion of total population that belongs to age-group i. Thus, the CDR tends to be high not only in populations with high age-specific death rates but also in populations in which a large proportion of the population belongs to age-groups that have relatively high death rates (e.g., old age-groups).

A widely used method to adjust per capita rates for age structure is age-standardization. The age-standardized death rate (ASDR) for a population is obtained by selecting an actual or hypothetical population as the 'standard' and assuming that the study population has the age structure of the standard population: the ASDR for population j is computed by

$$\mathrm{ASDR}^j = \sum_{i=1}^{n} M_i^j \cdot C_i^s \qquad [2]$$

where M_i^j is the death rate of age-group i in population j and C_i^s is the proportion of total population that belongs to age-group i in the standard population. If the ASDR is calculated for a number of populations using the same standard population, their differences in the ASDR are due to their differences in age-specific death rates only, and completely independent of their differences in age structure. The selection of a different standard does not change ASDR differences significantly unless the age pattern of mortality differs considerably among the study populations. This method is applicable to incidence rates of other age-associated events such as childbearing and migration, as well as proportions of the population with age-related characteristics such as marital status, labor force participation, and morbidity due to a particular disease. (For a more thorough explanation of age-standardization, see Section 2.2 of Preston et al., 2001).

Mathematical Expressions of Age Structure

Relationships between the age structure and demographic rates can be mathematically formulated (Bennett and Horiuchi, 1981; Preston and Coale, 1982) (*see* Population Dynamics: Theory of Nonstable Populations). The density function for population age distribution can be expressed as

$$c(a) = b e^{-\int_0^a r(x)\mathrm{d}x} p(a) e^{\int_0^a \lambda(x)\mathrm{d}x} \qquad [3]$$

where b is the crude birth rate, $r(x)$ is the population growth rate at age x, $p(a)$ is the proportion surviving from birth to age a in the period life table, and $\lambda(x)$ is the rate of net migration (immigration minus emigration) at age x. Note that this is

a relation between the age structure and demographic rates observed in the same period.

It may seem puzzling that the current age structure, which primarily resulted from population dynamics in the *recent past*, can be solely determined by *current* demographic rates. This paradoxical relationship can be understood by recognizing the role of age-specific growth rates in the equation. Age-specific growth rates reflect effects of past demographic changes on the current age structure (Horiuchi and Preston, 1988): the growth rate of population at age a and time t, $r(a, t)$, can be decomposed into the growth rate of the number of births, and cumulated changes in age-specific death rates and age-specific rates of net migration that the cohort aged a at time t has previously experienced:

$$r(a,t) = r_B(t-a) - \int_0^a \frac{\partial \mu(x,u)}{\partial u}\,\mathrm{d}x + \int_0^a \frac{\partial \lambda(x,u)}{\partial u}\,\mathrm{d}x \qquad [4]$$

where $r_B(t)$ is the growth rate of the number of births at time t, $\mu(a, t)$ and $\lambda(a, t)$ are the instantaneous age-specific death rate and instantaneous rate of net migration, respectively, at age a and time t, and the derivatives are assessed at $u = t - a + x$.

Equation [3] is a generalization of the age structure equation in stable populations (Doublin and Lotka, 1925; Lotka, 1998; originally 1939) (*see* Population Dynamics: Theory of Stable Populations, Population Dynamics: Classical Applications of Stable Population Theory). Consider a population in which the growth rate and age structure have been changing up to a certain point of time t. It can be shown that if the population is closed to migration and its age-specific birth rates and age-specific death rates remain unchanged after time t, the population will eventually become a stable population, in which the population growth rate and age structure remain constant over time. Simulations suggest that if the initial age structure of a human population is far from stable, it takes about a century or a little more for the population to become close to stability, but a few centuries to become almost exactly stable.

In a stable population, the density of age distribution at age a is given by

$$c(a) = b\mathrm{e}^{-ra}p(a) \qquad [5]$$

where b is the CDR, r is the growth rate of total population, and $p(a)$ is the proportion surviving from birth to age a, which is determined by age-specific death rates between ages 0 and a. In a stable population, these demographic measures are constant over time.

Equation [3] is used for demographic estimation from incomplete data (e.g., Bennett and Horiuchi, 1981; Preston and Bennett, 1983), eqn [4] is used for analyzing past changes in population growth and age structure (Horiuchi, 1991, 1995), and eqn [5] is used for demographic estimation from data on age distributions of historical populations before the demographic transition and populations in developing countries that are in early stages of demographic transition (United Nations, 1983: Chapter 7).

Age Structure and Population Growth

The age structure has strong effects on the increase or decrease of total population size in the immediate and near future. Even if several populations have the same size and same age schedules of fertility and mortality, a population with a higher proportion of population at peak childbearing ages (usually late 20s) is likely to have a greater number of births in the next several years, and a population with a higher proportion of children tends to have a greater number of births a few decades later when those children reach peak childbearing ages.

An indicator of the extent to which the age structure is conducive to population growth is the ratio of the size of stable equivalent (Keyfitz, 1969), denoted by Q, to the actual population size, N. The stable equivalent is a hypothetical quantity computed assuming that the age schedules of fertility and mortality at t_1 remain unchanged in the future and the population is closed to migration after t_1. Then the population would converge to stability at some time in the future, denoted here by t_2. The stable equivalent at t_1 is given by

$$Q(t_1) = N(t_2)\cdot \mathrm{e}^{-r(t_2-t_1)} \qquad [6]$$

where $N(t_2)$ is the size of the population at t_2. If the ratio of stable equivalent to actual population size at t_1, $Q(t_1)/N(t_1)$, is greater than 1, the population size would increase between t_1 and t_2 at the rates that are higher than the stable population growth rate r, due to the positive effects of age structure on population growth.

Another indicator is the population momentum, which is based on the hypothetical scenario that the fertility at t_1 instantly changes to the replacement level and then the age schedules of fertility and mortality remain unchanged, and there is no in- or out-migration (*see* Population Dynamics: Momentum of Population Growth). The population would eventually become a stationary population, which is a stable population the size of which remains constant ($r = 0$) over time. The population momentum is usually measured as the ratio of the size of the stationary population to the size of population immediately before the start of the replacement-level fertility (Keyfitz, 1971). The ratio may substantially deviate from 1, which indicates that even with the replacement-level fertility, the population may continue to significantly increase or decrease for some length of time, because the population increase or decrease in the near future has already been built in the age structure.

Abstract

Agency theory studies the problems and solutions linked to delegation of tasks from principals to agents in the context of conflicting interests between the parties. Beginning from clear assumptions about rationality, contracting, and informational conditions, the theory addresses problems of ex ante ('hidden characteristics') as well as ex post information asymmetry ('hidden action'), and examines conditions under which various kinds of incentive instruments and monitoring arrangements can be deployed to minimize the welfare loss. Its clear predictions and broad applicability have allowed agency theory to enjoy considerable scientific impact on social science; however, it has also attracted considerable criticism.

Foundations

Delegation and Conflict of Interest

A key tenet of economics is that specialization is productive. On the individual level, it is indeed often beneficial not to engage in a particular task oneself, but to delegate it to another person specializing in the task. Examples are counseling on legal matters, managing another person's funds, diagnosing and advising on illnesses, and precision-grinding a cylinder or machine tool. Delegating such tasks may be beneficial due to lack of time or knowledge of how to best perform the task (Laffont and Martimort, 2001). Yet, truly reaping the benefits of delegating a task to another person (an 'agent') is not always easy in practice. In *The Wealth of Nations*, Adam Smith, while praising the benefits of the division of labor and specialization, also provides what may be the first written account of the problems of delegation that the division of labor gives rise to. Referring to the directors of stock companies who as agents of the owners specialize in the day-to-day handling of the business, he (Smith, 1776: 700) observes that

> being the managers rather of other people's money than of their own, it cannot well be expected, that they should watch over it with the same anxious vigilance with which the partners in a private copartnery frequently watch over their own. … Negligence and profusion, therefore, must always prevail, more or less, in the management of the affairs of such a company.

Thus, Smith describes how different and even conflicting interests may lead to efficiency losses ('negligence and profusion') in the context of a situation of delegation in which principals cannot costlessly enforce the actions they prefer their agents to take, that is, where 'agency problems' exist. However, with few exceptions (particularly the debates of the 1930s on the economics of socialism and the separation of ownership and control in the modern corporation), awareness of agency problems in economics was virtually nonexistent until the end of the 1960. At that time, fundamental advances in economic analysis (economics of uncertainty and information, mechanism design, property rights) paved the way for a rigorous and systematic approach to these problems. Agency theory (or, 'principal–agent theory' or sometimes just 'incentive theory') is an integral part of contemporary microeconomics.

The canonical set-up of the theory is this. Two self-interested individual recognize potential gains from a trade, in which one (i.e., the principal) delegates a physical or mental task to the second (i.e., the agent), whose choice of actions and/or effort level affect the payoffs of both parties (Grossman and Hart, 1983; Jensen and Meckling, 1976; Ross, 1973). The agent is paid by the principal, who assumes the role of residual claimant in the relationship, that is, he holds the claims to net cash flows that result from differences between inflows and promised payments to other claim holders (Jensen and Smith, 1985). The agent and the principal hold different interests. For example, top managers acting as agents of the firms' shareholders may prefer 'empire building,' perks, leisure time, and so on, instead of maximizing shareholders' returns ('conflict in outcome-type preferences') (Holmström, 1979; Jensen and Smith, 1985). Likewise, managers may prefer engaging in capital expenditures that maximize the survival chances of the firm that pays their salaries, while shareholders will likely prefer them to go for high returns, but also typically more risky investments as they can diversify risk ('conflict in risk preferences') (e.g., Grossman and Hart, 1983). Or, yet again, managers may not plan to stay on for a long time with the firm in question and thus differ in the time horizon they consider in decision-making from (assumingly long-term oriented) shareholders ('conflict in time horizon') (e.g., Baker et al., 1994). Many other forms of conflicts of interests between the principal(s) and the agent(s) are obviously conceivable. All of these imply that the agent (or agents) may not act in the principal's best interest. Yet, these conflicting interests only become problematic when combined with information being asymmetrically distributed between the principal(s) and the agent(s).

Asymmetric Information, Hidden Characteristics, and Hidden Action

The delegation of a task is often motivated by the principal lacking knowledge, abilities, or skill to perform the task

 http://dx.doi.org/10.1016/B978-0-08-097086-8.73038-8

themselves, knowledge differences that explain why gains from trade exist in the first place. However, it also implies that the principal faces a disadvantage with respect to judging the agent's true knowledge and/or efforts in carrying out the delegated task. For example, patients typically cannot fully ascertain the physician's knowledge, abilities, and skills. They may rely on the academic degrees the agents hold, their reputation, or the like; however, only the agents know the true state of their knowledge, abilities, and skills. The situation is complicated by self-interested agents potentially deliberately hiding their true qualities (e.g., a lack of appropriate skills for conducting the task at hand) or even falsifying signals (e.g., faking their CV or the degrees they hold) in order to get a job and to earn the related rents. Therefore, when informational asymmetry is present already before the principal hires an agent this gives rise to the so-called 'hidden characteristics' problem. It is one of the core problems in delegation under conflicting interests and information asymmetry between the parties studied by agency theory.

Even if the principal is perfectly informed about the characteristics of the agent(s), she may, nevertheless, face an information disadvantage with respect to the actions taken by the agent(s). More precisely, the disadvantage (i.e., informational asymmetry) concerns which action (or effort level) the agent actually took, whether it was the right one given the circumstances, and exactly which circumstances pertained (Grossman and Hart, 1983; Holmström, 1979). For example, the sales of a salesperson on a local market are influenced by stochastic influences, such as changes to local demand, that may be hard or simply too costly to ascertain by the principal (the firm who employs the salesperson). Of course, agents are likely to hold superior knowledge concerning the true actions or efforts they exert in carrying out the task. Agents may exploit this information asymmetry by engaging in actions not valued by the principal or withholding effort or other forms of 'hidden action.' This is often captured by the notion that the agent experiences 'disutility of labor,' which is somewhat misleading as it implies that agents are lazy. They may be, but the more general interpretation is that agents prefer dedicating effort to activities they choose themselves.

The upshot of the above is that the principal may face informational disadvantages either ex ante (i.e., 'adverse selection,' 'hidden information'), that is, in the contracting stage of the relationship, or ex post ('moral hazard,' 'hidden action') when the agent may carry out the delegated task in a manner or with an intensity diverging from what would maximize the principal's payoffs. Further complicating is the fact that both problems may appear within the same relationship. For example, when looking for legal advice from a lawyer, the client may neither know enough to fully judge alternative lawyers' abilities, knowledge, and skill nor may she/he be able to observe and properly judge the efforts made by the lawyer chosen. Under conflicting interests and when the principal is either not knowledgeable of the task she wishes to delegate and/or cannot observe the agent's characteristics and actions, the principal faces problems of hidden characteristics or hidden action (or both). Hence, both information asymmetry and conflict of interest are necessary ingredients for a 'principal–agent problem' to exist.

Core Insights and Predictions of the Agency Model

The Linear Agency Model

The workhorse model of agency theory, the 'linear model' (Holmström and Milgrom, 1991; see also Holmström, 1979, for a seminal contribution that is also echoed in the following) studies a two-party setting: one principal and one agent. Both are assumed to be self-interested, behave rationally, and maximize their utility. Due to information asymmetry ex post, the principal is unable to contract over the agent's actions (which the principal assumingly cannot observe), but only over the output z of the agent's actions. (In agency theory, all observable variables are contractible.) For convenience, most agency theorists think of the agent's actions as his effort e, that is, alternative actions correspond to different effort levels (e.g., Holmström, 1979) and the terms effort and action are thus used interchangeable in much of the literature. The result z in turn is assumed to depend linearly on the sum of the agent's choice of effort e and some stochastic influence from the environment θ. For simplicity, the basic model assumes this external influence to be standard-normally distributed with an expectation of zero. Both, the distribution and the expectation, are known by both parties, whereas the true effort e exerted by the agent and the actual state of the environment θ are only known to the agent; the principal can only observe the result z caused by both e and θ. The principal is thus assumed to be unable to ascertain whether a good result z is due to the agent's high-effort level e or due to 'luck' (θ); hence, she/he faces a problem of hidden action/moral hazard.

The interaction between the principal and the agent starts with the principal contracting with the agent about a wage W, which is comprised of some proportion β of the result z generated by the agent (potentially plus some fixed salary component W_0). The share of the result z that the principal agrees to pay the agent (i.e., the β) is referred to as 'incentive intensity.' As the true effort e cannot be observed, the agent's wage W must be based on the result z obtained (which is influenced by the stochastic environment). Therefore, any β larger than zero implies that the agent is exposed to risk with respect to his/her remuneration. And here comes another assumption of the (basic) agency model into play: The risk aversion r_A of the agent. While the principal is assumed to be risk neutral (she is able to diversify risk, e.g., by holding a market portfolio of relationships), the agent is assumed to be risk averse as his payoffs are linked to the particular relationship (e.g., Grossman and Hart, 1983). Risk aversion implies that the agent will ask for a premium in order to accept a contract offered by the principal based on the risky result z.

This risk premium reduces the surplus, but does not give the agent extra utility. Thus, the larger the risk premium, the smaller the total value created in the relation (i.e., the sum of the monetary equivalents of the utilities of the principal and the agent). The size of the risk premium depends on both the degree of risk aversion of the agent r_A and the riskiness of the wage (i.e., the variance in the wage due to the environment's impact ($\mathrm{Var}(W) = \beta^2\,\mathrm{Var}(\theta)$)). Thus, β has to solve two tasks: providing incentives to the agent to work hard and insurance against risk (note: literature unfortunately also uses the term 'uncertainty' to denote the stochastic nature of the agent's payoffs, which we do not follow here as it clutters the

differences between randomness and true uncertainty in the sense of Frank Knight, that is, outcomes for which no distribution and expected value are known). It is, therefore, usually impossible under information asymmetry to handle both tasks optimally (Holmström, 1979). Therefore, any solution is inefficient ('second-best') as compared to a hypothetical first-best solution in which the principal would bear all the risk and the agent would be paid on his/her efforts only.

In addition to the (risky) payoffs associated with the relation, agents are expected to consider their costs (Grossman and Hart, 1983). Agents are assumed to have exponentially growing disutility of engaging in effort ($C(e)$). Principals in turn need to take this into account when solving their own optimization problem concerning the optimal β. As Holmström and Milgrom (1991) show, this can be done neatly by starting out from the certainty equivalents of both parties. A certainty equivalent is the certain value that makes an individual indifferent in terms of utility between obtaining the 'risk-free' certain value and a risky 'lottery' value. For the agent, the certainty equivalent corresponds to the wage minus the risk premium minus the costs (i.e., $CE_A = W_0 + \beta \bullet e - ½ \bullet r_A \bullet \beta^2 \bullet \mathrm{Var}(\theta) - C(e)$). Taking the first derivative of this term to e and then setting the expression to zero and solving for β yields the helpful term of $\beta = C'(e)$, that is, the agent's optimal choice of e is where marginal revenue equals marginal cost. The optimizing behavior of the agent implies that his efforts e are a function of β. Based on this insight only a few mathematical optimization steps are now necessary to solve the principal's problem, that is, to get from the task to maximize the total certainty equivalent for both parties (max $CE_{\mathrm{Total}} = P(e(\beta)) - C(e(\beta)) - ½ \bullet r_A \bullet \beta^2 \bullet \mathrm{Var}(\theta)$) to the optimal incentive intensity (denoted as β^*) (for the details of the mathematical derivation see e.g., Milgrom and Roberts, 1992: pp. 222n; and for the original formulation, Holmström and Milgrom, 1991).

The resulting expression $\beta^* = P'(e)/[1 + r_A \bullet \mathrm{Var}(\theta) \bullet C''(e)]$ suggest that the optimal β depends on four factors: (1) The more sensitive the payoff to the principal on changes in the agent's efforts or actions ($P'(e)$), the larger should be β^*; (2) the stronger the agent's risk aversion r_A, the lower the β^*; (3) the larger the riskiness of the results obtained by the agent due to environmental influences $\mathrm{Var}(\theta)$, the lower the incentive intensity; and (4) the stronger the agent's discretion regarding the choice of activities ($\partial e/\partial \beta = 1/C''(e)$), that is, the lower his/her costs of acting in a manner functional for maximizing the principal's payoffs ($C''(e)$), the larger the β^*.

Core Insights

The set of insights what determines β^* has become known in literature under the label of the 'incentive intensity principle.' It is one of the core contributions of agency theory to the understanding of how principals can set incentives and design-monitoring schemes in order to minimize the welfare loss ('agency costs') resulting from conflict of interest and information asymmetry ex post. In short, β^* is determined by incentive elasticity of profits (e.g., there may be tasks where strengthening incentives does not lead to more effort being supplied); the risk tolerance of the agents (e.g., agents that are high in risk aversion will demand a high risk premium); the effort elasticity of incentives (e.g., some agents may have work/leisure tradeoffs such that they are not easily incentivized); and the measurability of outputs (if outputs are very costly to measure, it may be counterproductive to tie pay to outputs).

A key application of the linear model concerns when to use additional information γ in the incentive design, such as, for example, the sales performance of other sales representatives when incentivizing a particular salesperson or the performance of similar firms in the industry when judging top-management's efforts, and so on. The extended model demonstrates that if the additional information gathered is not 'informative' about the focal agent's true effort, that is, if the additional information γ used has a covariance of zero with the state of the environment θ, then including the additional information in the wage contract with the agent is unreasonable. Including it under such conditions only adds noise, which makes drawing conclusions about the agent's true effort level or actions even harder (Milgrom and Roberts, 1992). Therefore, the 'informativeness principle' calls for including additional available information only if it allows reducing noise.

The 'equal compensation principle' stems from yet another extension of the basic model. This extension renders the model more realistic by allowing the focal agent being responsible not only for a single task or single-dimensional task, but for multiple tasks or multidimensional tasks, with performance on some tasks or dimensions easily measureable and others only difficult or prohibitively expensive to assess. Holmström and Milgrom (1991) show that, under such conditions, agents will shift their effort to those tasks/dimensions that are measured (and rewarded) by the principal(s) at the detriment of other tasks (or other dimensions of the task) that are too expensive to assess. For example, the agent may focus on her/his results looking good in terms of the financial performance achieved, but neglect other nonfinancial and (may be only qualitative) aspects, such as performance with respect to customer satisfaction, environmental or social dimensions of a task, and so on. The extended model thus suggests two consequences: (1) grouping easy-to-measure tasks together instead of spreading them over multiple individuals, and to provide a low β to those individuals engaging in the tasks with the hard or impossible to measure dimensions/tasks, and (2) choosing only a low β if the task dimensions cannot be separated organizationally on multiple individuals and agents thus have to carry out multidimensional tasks with some dimensions costly to measure but essential to the principal.

Finally, the 'monitoring intensity principle' highlights the complementarities of incentive provision and monitoring in addressing hidden-action problems. While the basic model treats the variance with which efforts are measured as outside the principal's control, it is in many cases more realistic to assume the principal to be able to improve measurement by spending resources on, for example, more detailed data collection, a lower span of control of supervisors allowing them to closely monitor individual employees, and so on. While all of these actions are costly to the principal, they improve the principal's information about how the agent performs. By including the costs for measurement in the optimization problem, the extended model suggests that more resources should be spent on measurement when the incentive intensity is higher. Hence, high incentive intensity and careful

performance measurement are complementary (Milgrom and Roberts, 1992).

Besides these exemplary extensions, agency theorists have developed a great number of other refinements of the model that relax certain assumptions and render the model more realistic. For example, scholars have refined the model to allow for multiperiod settings, risk-averse principals, risk-neutral agents, nonlinear production functions, subjective versus objective performance measures, or to expand the model to comprise more than two parties – that is, multiple principals and/or agents (e.g., Baker et al., 1994; Milgrom and Roberts, 1992).

The basic agency model (and many of its extensions) provides insights for handling both ex post as well as ex ante information asymmetry. For example, it suggests that principals offering agents a contract with a $\beta > 0$ are likely not only to reduce problems of hidden action, but can also already ex ante trigger that agents with lower abilities and skills prefer not to accept such a performance-contingent contract and to, for example, look for other employment opportunities where they are given a fixed salary. Thus, firms switching from paying their employees a flat wage can be expected to benefit from two effects: First, an increase in the effort level exerted by the employees already employed by the firm ('incentive effect') and second, a beneficial change in the pool of new applicants for positions with the firm (i.e., the 'sorting effect' of variable incentive schemes).

Principals may also rely on increased information gathering already ex ante about potential agents in the contracting stage to reduce information asymmetry. Job interviews are one example of such information gathering or screening activities ex ante that aim at reducing the hidden-characteristics problem. Agents themselves may take the initiative by signaling their true ('good') characteristics to the principal(s), that is, reducing information asymmetry between them and the principal(s) through such instruments like, for example, providing warrantees for used cars that they wish to sell in the example of car dealers, or investing into acquiring academic degrees in case of agents seeking a job.

Exemplary Applications and Contributions

Conflict of interest and asymmetric information are widespread phenomena in cooperative activities among individuals (Holmström, 1979; Jensen and Meckling, 1976; Ross, 1973). Thus, it is not surprising to see agency theory being applied to the study of a wide range of relationships within labor market (i.e., labor market economics) and business contexts (i.e., personnel economics), as well as in sociology or political science research. Discussing the many applications of agency theory is beyond the scope of this article; in fact, merely scratching the surface of this huge body of literature is a daunting challenge.

By looking at relationships between two or more cooperating individuals in terms of a 'nexus' of explicit or implicit contracts (e.g., Alchian and Demsetz, 1972; Jensen and Meckling, 1976), agency theorists were among the first scholars who opened up the 'black box' of firms and organizations, and contributed the explaining rationales and workings of other kinds of economic organization (i.e., various kinds of nonfirm contracting arrangements). An early influential stream (Alchian and Demsetz, 1972) conceptualized firms as efficient responses to agency problems caused by 'team production' in which individual productivity is costly to observe, but the team's output is not. In this situation, it makes sense to appoint a monitor who holds residual income rights to the team's output, because this means that he will undertake an efficient level of monitoring. Thus, the monitor is also the owner of the firm and holds right to discipline team members – a rudimentary theory of why there are firms in a market economy (see Holmström, 1982, for important refinements and extensions).

These contributions represent marked scientific progress over the previously dominant perspective of firms as production functions with their own preferences and decision-making presumably corresponding to a single individual. Agency theory has profoundly changed how economics and business research think about firms and organizations in general in fields such as corporate governance, human resource management (in particular: remuneration), strategy implementation, performance measurement, organizational control, accounting as well as phenomena affecting intersections of multiple of these fields.

Agency theory (and derivations thereof) sees application to a growing number of research fields within political science and sociology (see Kiser, 1999, for a detailed review). Scholars in political science have applied (often more or less adapted versions) of agency theory to a wide array of topics, with particular emphasis on studying legislatures and policy implementation. In an early application, Rose-Ackerman (1975), for example, uses agency theory to study corrupt dealings in the government contracting process. Others have focused on how 'red tape' can serve a monitoring function to achieve that policy decisions by unelected bureaucratic officials are responsive to the preferences of citizens. Adams (1996) in turn provides an example of the theory's use within sociology to study the relationship between patrimonial states and colonial trading companies in the Netherlands and England.

Criticisms and Limitations

Agency theory has attracted considerable criticism from various authors and scholarly fields. In particular, numerous authors have criticized the assumptions underlying the standard agency model as too restrictive, that is, as not being generalizable to the overwhelming part of humans, but as rather being particular to just a subset of individuals.

Given and State Independent Utility/Risk Functions

Empirical and experimental research suggests that the von Neumann and Morgenstern utility functions underlying agency theory are likely not to be as generally applicable, as was originally hoped. For example, Prospect Theory advanced by Daniel Kahneman and Amos Tversky in response to empirical evidence questioning the von Neumann and Morgenstern utility theory suggests that individuals will consider their current wealth when evaluating how to act, implying that the same individual may sometimes be risk averse, risk neutral, or even risk seeking depending on the state of his/her personal

wealth. So far, these insights have not yet been incorporated into agency theory.

Complete Contracting

Agency theory assumes complete rationality of the parties involved, implying that the contracts between the principal(s) and the agent(s) will contain all available information and that the terms stipulated in the contract will consider all possible future situations (the so-called 'complete contracts'). Hence, while principal(s) and agent(s) are assumed to differ in terms of the information about the characteristics of the agent(s) or their actions, the theory assumes that each of the parties makes full use of the information available to it in designing the contract and in deciding on how to act, respectively. Agency theory thus – as opposed to transaction cost economics – abstracts from potential costs for incorporating information into the contracts as well as from the possibility that contracts may be incomplete simply due to insufficient knowledge about all potential future situations or actions possible. While Ross (1973: 135) submits that under the assumption of complete contracts "the problem is considerably simplified but much of the interest does remain," agency theory's underlying assumption thus, nevertheless, hampers its usefulness for the study of a number of highly important real-world phenomena. Entrepreneurship, for example, while undoubtedly a core economic phenomenon, is hard to study when allowing only for risk – that is, probabilistically known future states that hence can be included in a complete contract, but not uncertainty in the sense of Frank Knight, which defies standard probabilistic accounts, but which is part of the very nature of entrepreneurial activities. Hence, such fundamental questions of what the principal should want the agent to do and how the principal actually became the principal in the first place have been rather sidelined in agency theory.

Self-Interest/Opportunism

Some authors have pointed out that agency theory may paint a too dark picture of human nature by assuming that individuals behave opportunistically. Perrow (1986) even went as far as claiming that agency theory is 'not only wrong but dangerous' (p. 11) – a theme echoed by a host of writers after the onset of the current financial crisis claiming that agency theory reflects a misguided libertarian ideology and would prompt the adoption of an overly cynical view of human nature. They warn that when this view is generalized, for example, through the teachings of economists in universities and business schools, there is a risk that important prosocial behaviors are crowded out or that a self-fulfilling prophecy might result from assuming individuals to be opportunistic. Moreover, some scholars have pointed out that the theory does not devote sufficient attention to the potential consequences of the principal's opportunism, in the sense that he may try to cheat on the agent in the performance evaluation or reward. However, given that the theory assumes complete contracting, i.e., that the agent might appeal to a third party – e.g., a court – for enforcement of the contract, this criticism seems rather misguided.

Neglect of Intrinsic Motivation

The phenomenon of a 'crowding out' of task-autonomous motivation (often called 'intrinsic motivation') largely associated with the pioneering works by Edward L. Deci and Richard M. Ryan has attracted massive interest among scholars in psychology, education research, and lately also in economics, and management research. While it seems rather well established within education research that administrating incentives that are perceived as controlling undermines the preexisting task-related autonomous motivation of the agent to engage in the task – for example, due to enjoyment of carrying out the task or due to fully internalized norms and values of the agent – the jury is still out when it comes to the phenomenon's existence and magnitude in common business settings. Several studies in economics (e.g., Lazear, 2000) reported increases in employee's engagement in routine or mundane activities – such as, for example, the installation of auto glass – when providing performance-contingent incentives for these activities. However, the existing evidence on motivation crowding suggests that it is likely that the phenomenon pertains to nonmundane tasks in business situations. Existing agency models thus are likely to require adaptation to take the interaction of incentives (and monitoring) with task-autonomous motivation of the agent(s) for nonmundane tasks explicitly into account. This might lead to more nuanced versions of the incentive and monitoring intensity principles.

Dominance of Linear Models with Small Number of Players in Agency Models

The common linear models used in much of agency theory provide great tractability. Yet, linear contracts may not be optimal contracts and the generality of the findings may thus be limited. Similarly, limiting the models to only a small number of principals and/or agents is necessary to keep model complexity to a manageable level. However, real-world social behavior, in particular in groups of 'agents,' is likely to be much more complex than suggested by models focusing only on a small number of players.

Practical Usefulness of Agency Insights

A number of scholars have questioned the practical applicability of (some of) the insights obtained from agency models. First, in practice, managers and HR professionals often lack the information assumed available in principal–agent models, such as, for example, the marginal effect on the principal's payoffs of an increase in the agent's effort level by one unit, risk tolerance, or the agent's responsiveness to incentives. Measurement of these variables, in practice, is still a thorny issue, reducing many of the highly-interesting theoretical insights generated by agency theory to mere rough guidelines from a practitioner's perspective. Second, contrary to what agency theory typically assumes, employment contracts and many other contracts are subject to external restrictions beyond the principal's control, such as labor laws, generating outcomes different from those analyzed in the theory. Third, contracting may, in practice, not necessarily correspond to the situation assumed in agency theory with the principal proposing

contracts on a take-it-or-leave-it basis. Rather, some bargaining between the principal(s) and the agent(s) will take place. Thus, it may not be wise for principals, in practice, to propose to their agent(s) the optimal contract right away, but rather to propose one that will – considering the bargaining to take place – lead to the optimal contract (or one that is close enough). As agency theory does not provide guidance here, insights from bargaining theory may be necessary and valuable complements to practitioners.

In Defense of Agency Theory

While agency theory's assumptions have attracted considerable criticism from many sides, they do possess a particular strength: their explicit nature. This allows systematically relaxing them, that is, adapting them to assumptions deemed more 'realistic.' Thus, while the assumptions underlying the basic agency model are likely not representative of humans in general, the theory provides for a framework that allows modeling a large number of more- or less-diverging assumptions – and testing the need for, benefits of, and shortcomings of alternative governance modes, as well as incentive and monitoring schemes under these assumptions. The explicit nature of agency theory's assumptions thus is an asset facilitating cumulative knowledge growth and continuous refinement of the recommendations developed by scholars.

The use of the theory itself outside economics and business administration has triggered criticism, sometimes sparked outcries of 'economics imperialism.' Yet, it is important to note that agency theory, while first gaining popularity in economics, is conceptually closely linked in many ways to earlier work in sociology, such as Max Weber's works. Moreover, agency theory has not only strongly influenced research in political science and sociology, but has seen itself being adapted and transformed to better fit their different disciplinary contexts (Kiser, 1999). This holds particularly true for the variant of agency theory typically employed in sociology, which can be seen as an amalgam of Weberian sociological insights and the economic agency model, which implies a much broader conception of both the micro- and the macrolevels (see Kiser, 1999, for an excellent discussion of this topic).

Agency theory's popularity among scholars and, in particular, its seemingly simple 'lesson' that agency problems can be largely cured by relying more on performance-contingent incentives instead of fixed salaries, have contributed significantly to the marked trend toward merit-based payment and promotion schemes in recent years. The 'lesson' that one needs to 'pay for performance' in order to obtain superior results made it into MBA curricula, consultants' recommendations, and ultimately into management practice at most larger firms in North America and Europe. Hence, agency theory can be seen to have had a tremendous practical impact – which, as mentioned, has spawned criticism of the theory. However, a closer look at the scientific debate about agency problems and the ways to address them suggests that the incentive practices used are at best a bad copy of what agency theory recommends doing. Thus, already the basic linear model shows that strong variable incentives (a high β) are by no means recommendable under all circumstances. And the extensions of the basic model introduced into the literature over the course of the past 30 years further strengthen the conditionality under which 'high-powered' incentives are optimal – and when they promise to fail (e.g., Baker et al., 1994; Holmström and Milgrom, 1991). Surprisingly, however, these insights seem to have had little impact on compensation practices in banking and the public debate about them. Overall, thus agency theory, while having inspired practice, has unfortunately not seen a more widespread application of one of its most important insights: the conditions necessary for using high-powered incentives.

Conclusion and Outlook

Agency theory studies the problems and solutions linked to delegation of tasks under information asymmetry and conflicting interests between two or more parties. It assumes rationality and self-interest of the parties involved and deals with both problems of ex ante ('hidden characteristics') as well as ex post information asymmetry ('hidden action'). Agency models provide a number of very important recommendations for designing contracts, such as the incentive intensity and the monitoring intensity principles. The theory's broad applicability (Holmström, 1979; Jensen and Meckling, 1976; Ross, 1973) allows agency theory to enjoy tremendous scientific impact both within economics and management research as well as beyond. At the same time, it also has attracted considerable criticism. Most of this criticism focuses on the assumptions underlying agency theory, and in particular, those underlying simple models. These assumptions are often very restrictive to foster tractability of the problems in mathematical terms. Some of the polemical criticisms of it are however misguided. Recent years have witnessed considerable effort in economics and management research addressing some of the theory's major limitations, and some of the criticisms do not apply to the 'derivatives' of economic agency theory found in sociology and political science (Kiser, 1999).

Abstract

Agenda setting explicates Walter Lippmann's thesis in *Public Opinion* that the news media are a major link between the world outside and the pictures in our heads. In the decades since the seminal Chapel Hill study, evidence of this media influence has been found worldwide for public issues, perceptions of public figures, and other topics. This evidence also explicates the underlying psychology of these agenda-setting effects and the consequences of these media effects for attitudes, opinions, and behavior.

The news media have a major influence on the focus of public attention, the specific issues that members of the public regard as most priority at any moment. Beyond this influence, the news media also direct our attention to specific aspects of these issues. This combined influence of the news media on the public's attention to and learning the key details of the major issues of the day is referred to as the agenda-setting role of the news media.

The intellectual father of agenda-setting theory is Walter Lippmann, whose book, *Public Opinion* (1922), began with a chapter titled 'The world outside and the pictures in our heads.' The central thesis of the book is that the news media are the primary bridge between the vast array of events in the external world and the truncated views of these events in our minds. As Lippmann noted, our opinions and behavior are a response to these pictures in our heads, not the larger outside world.

Nearly half a century later, during the 1968 US presidential election, Lippmann's observations were the basis of the seminal Chapel Hill study (McCombs and Shaw, 1972) that introduced the theory of agenda setting. The core concepts of this theoretical metaphor are a media agenda, a public agenda, and the transfer of salience of the items on the media agenda to the public agenda. In agenda-setting theory, salience refers to the prominence and perceived importance of items in the news. The term 'agenda' as it is used here is a neutral descriptive term, quite the opposite from its meaning in the phrase 'to have an agenda.' The transfer of salience from the media agenda to the public agenda is the inadvertent by-product of the necessity of the news media to focus their attention on a small number of topics at any particular point in time. In other words, agenda-setting effects are an incidental result of people's use of the news media. However, as we shall see, the strength of these agenda-setting effects can vary considerably. The public are not a tabula rasa waiting to be programmed by the media.

Comparing Media and Public Agendas

To test the central assertion of agenda-setting theory that the media agenda sets the public agenda, the Chapel Hill study compared the salience of five major issues defining the media agenda with the salience of these issues on the public agenda of undecided voters. The focus on undecided voters in Chapel Hill was a strategic decision about the most likely setting for media effects because the conventional wisdom of the time held that the media had little impact on the public due to their selective exposure to compatible political messages (Klapper, 1960). McCombs and Shaw reasoned that selective exposure should be minimal among undecided voters and a more likely setting for media effects.

In the Chapel Hill study and subsequent research, the media agenda is defined by the pattern of news coverage over a period of several weeks. Systematic content analysis reveals which issue receives the most coverage, which the second most coverage, etc. In other words, the issues in the news can be rank-ordered according to the amount of coverage that they receive. The public agenda most often is determined by the long-standing Gallup Poll question, 'What is the most important problem facing this country today?' The aggregate responses to this question or similar measures of the perceived importance of the issues of the day also can be rank-ordered from most to least frequent.

In Chapel Hill, McCombs and Shaw compared the salience of five major issues defining the media agenda with the public agenda among undecided voters and found a near-perfect match in their rank-order (+0.97, where the maximum value of this correlation coefficient used to index the strength of agenda-setting effects is +1.0). The empirical correlations among general populations are somewhat lower. A year-long study during the 1976 US Presidential campaign found a peak correlation of +0.63 between the television agenda and the public agenda during the spring primaries (Weaver et al., 1981). In the 1995 local elections in Pamplona, Spain (McCombs, 2014), there were substantial matches between the public agenda and the agendas of both local newspapers (+0.90 and +0.72, respectively) and television news (+0.66). Wanta and Ghanem's (2000) meta-analysis of agenda-setting studies found a typical correlation of +0.55 between the media agenda and the public agenda.

There are now hundreds of empirical studies worldwide documenting agenda-setting effects. These studies have examined the presentation of a wide variety of public issues – and a handful of other topics – by various combinations of newspapers, television, and other communication media and the public's response to these media agendas in both election and nonelection settings in Asia, Europe, Australia, and South America, as well as in the USA and Canada. For rigorous tests of

agenda-setting theory's assertion of a causal link between the media agenda and the public agenda – that is, the media agenda sets the public agenda – these effects also have been produced in controlled laboratory experiments (Althaus and Tewksbury, 2002; Conway and Patterson, 2008; Iyengar and Kinder, 1987).

In the new media landscape, a wide variety of Internet channels have joined the chorus of media voices and demonstrate agenda-setting effects among the public similar to those found over the decades for newspapers and television (Tran, 2014). With this vast expansion and transformation of the communication landscape, some observers have predicted the diminution, if not the actual disappearance, of agenda-setting effects on the scale that we have observed them over the past half century (Chaffee and Metzger, 2001). Despite the popularity of speculation on this possibility, the overwhelming preponderance of the evidence to date suggests that the agenda-setting role of the communication media endures.

Although there is divergence in the contemporary media-use patterns among different generations, two statewide surveys in the US found little difference in agenda-setting effects among the younger, middle, and older generations (Coleman and McCombs, 2007). Greater attention to the Internet and much less attention to traditional media among younger adults had little impact on agenda setting. Particularly compelling is the comparison in Louisiana of the issue agendas of low and high Internet users to the issue agenda of the state's major newspapers. For low Internet users, the correlation with the newspaper agenda is +0.90. For high Internet users, the correlation is +0.70.

Both the strength of agenda-setting effects in past decades and their continuing strength in the contemporary media setting result from long-standing patterns of behavior in the media and among the public. The high degree of homogeneity among media agendas found in the original Chapel Hill investigation continues in contemporary settings (Boczkowski, 2010). Among the public, strong agenda-setting effects across the population result from civic osmosis, the continuous exposure to a vast sea of information from many channels of communication (McCombs, 2012; Stromback and Kiousis, 2010; Webster and Ksiazek, 2012). For most people, this exposure ranges from habitual and deliberate attention to some news channels to incidental exposure to other news channels in the course of daily life. In tandem with the homogeneity of these news channels, the outcome is a high degree of consensus on the major issues of the day.

A Second Level of Agenda-Setting Effects

Agenda-setting theory focused initially on the objects defining the media and public agendas. The term 'object' is used here with the same meaning as the term 'attitude object' in social psychology. In agenda setting, the objects most frequently studied are public issues and political figures. However, any set of objects that is of interest can be analyzed, such as institutions, corporations, or brands of goods. Moving beyond the focus on objects, media messages about public issues and other objects include descriptions of these objects. In abstract terms, objects have attributes. Just as these objects vary in salience, so do the attributes of these objects. When the media present an object – and when the public thinks about and talks about an object – some attributes are emphasized. Others are mentioned less frequently, some only in passing.

Just as there is an agenda of objects, there is an agenda of attributes for each of these objects, an agenda on which the attributes can be rank-ordered according to their frequency of appearance. The influence of the media on the relative salience of these objects among the public is the first level of agenda setting. The influence of the media on the relative salience of these objects' attributes is the second level of agenda setting.

Images of political leaders among the public afford examples of attribute agenda setting (McCombs, 2014). In the 1994 mayoral election in Taipei, Taiwan, the correlations ranged from +0.59 to +0.78 for six comparisons between voters' images of the three candidates – their attribute agenda – and news coverage of these attributes – the attribute agenda in two major daily newspapers. Here the substantive attributes of these candidates included personal qualities, such as ability, experience, and political style, as well as nonpolitical attributes, such as personality, integrity, and speaking ability.

Beyond the substantive attributes of a candidate or other object in the news – the specific traits or characteristics that describe the object of attention – there is a second dimension of the attribute agenda, the affective tone associated with each substantive attribute. When the media and the public describe an object in terms of its substantive attributes, these attributes are presented in positive, negative, or neutral terms.

In the 1996 Spanish general election, both the media attribute agendas and the public attribute agendas for these candidates were organized in terms of both their substantive and affective dimensions. In this demanding test of attribute agenda-setting effects, there was substantial correspondence between the news coverage in seven news media of the three major candidates and their images among Pamplona voters. In the analysis, the combination of five substantive categories and three levels of affect resulted in a 5×3 matrix describing each candidate's attribute agenda. For six comparisons of the voters' attribute agendas for each of the three candidates with the attribute agendas of two local newspapers, the median correlation was +0.70. For six comparisons with two national newspapers, the median correlation was +0.81, and for six comparisons with two national TV news services it was +0.52.

Attribute agenda setting also occurs with public issues (McCombs, 2014). Some aspects of issues are emphasized in the news and in how people think and talk about issues. Other aspects are less salient. News coverage in Japanese newspapers about global environmental problems in the months prior to the 1992 United Nations Rio de Janeiro conference resulted in a steady increase in public agreement with the media agenda. In February, the match was +0.68 and by April, +0.78. A similar pattern was found during a 3-week period prior to a local tax election in the USA. Correspondence between the voters' attribute agenda, the relative salience of various aspects of the issue, and the local newspaper's framing of the local tax increased from +0.40 to +0.65. The match with the political advertising on the issue increased from +0.80 to +0.95. A longitudinal study of a Swiss referendum on changing the country's political asylum law also found strong attribute agenda-setting effects evolving among persons reporting heavy

reliance on newspapers and TV for public affairs information. By the third wave of interviewing, the match between the media's attribute agenda and the public's attribute agenda was +0.92. The news media have a significant influence on both object salience and attribute salience.

Exploring a Third Level of Agenda-Setting Effects

Returning to Lippmann's phrase "the pictures in our heads," the first level of agenda setting – the transfer of object salience from the media agenda to the public agenda – answers the question "What are the pictures about?" The second level of agenda setting – the transfer of attribute salience from the media agenda to the public agenda – answers the question "What are the principal characteristics presented in these pictures?" The emerging third level of agenda setting brings us closer to answering the question "What are the pictures?" Beyond the transfer of salience for objects and attributes taken individually, can the news media transfer the salience of a more integrated image, a more comprehensive picture of an object and its attributes?

In the research to date on the first and second levels of agenda setting, the elements that have been investigated are discrete objects and attributes. That is, the objects have been disaggregated from their larger context and rank-ordered according to their frequency of appearance in news stories and in survey respondents' answers to the most important problem (MIP) question or a similar measure of object salience. At the second level of agenda setting, the attributes describing political figures, issues, or other objects have been disaggregated from their larger context and rank-ordered according to their frequency of appearance in news stories and in survey respondents' answers to questions measuring attribute salience. However, in the actual news stories and in respondents' descriptions, these elements are bundled together. Attributes are linked to objects and typically more than one attribute appears in a news story or a respondent's reply.

The third level of agenda-setting effects theorizes that the salience of these bundled relationships among objects and attributes are also transferred from the news media to the public. Theoretically central to this perspective is an associative network model of memory. Rather than conceptualizing our mental representations as a hierarchical or linear structure as implied in the traditional understanding of agenda-setting theory, this associative network model holds that the representation operates pictorially, diagrammatically, or cartographically (Braddon-Mitchell and Jackson, 2007; Cummins, 1996). In this network model, individuals' cognitive representations are presented as a network-like structure where each element is connected to numerous other elements.

To explore whether the media can bundle a variety of elements and make them salient in the public's mind simultaneously, Guo and McCombs (2011a) reanalyzed data from a previous study that had found strong attribute agenda-setting effects based on a traditional analysis of discrete sets of political candidates' attributes. In the original study of the images held by voters of four statewide political candidates in the USA (Kim and McCombs, 2007), the overall correspondence between the media attribute agenda and the public attribute agenda was +0.65. Similar correlations were found when the attribute agendas of each of the four candidates were analyzed separately. Using the statistical technique of network analysis to analyze the pattern of bundled attributes on the media agenda and the public agenda – that is, an investigation of third-level agenda-setting effects – the correlation was +0.67, a result that is statistically very similar to the original analysis. Of course, the networked representations of these agendas are a much richer picture of these attributes. These results from the bundled 2002 Texas election data were replicated with new data collected during the 2010 gubernatorial election and yielded a correlation of +0.71 (Guo and McCombs, 2011b). In the 2012 US presidential election, Vargo et al. (2014) compared the correspondence of Twitter network issue agendas from mainstream media, partisan media, and the supporters of Barack Obama and Mitt Romney.

Explaining Agenda-Setting Effects

News reports are a limited portrait of our environment and, as Lippmann noted in *Public Opinion*, create a pseudo-environment to which the public responds. Often there is little correspondence between the pattern of news coverage and underlying historical trends.

Shortly after the Chapel Hill study, Funkhouser (1973) compared the responses to the Gallup Poll's MIP question across the entire decade of the 1960s with the pattern of coverage on those issues in the news magazines and found a high degree of correspondence, a correlation of +0.78. Most importantly, he added a third set of data, statistical indicators of the 'reality' of those issues across the 1960s. Funkhouser (1973: p. 72) noted that "the patterns of media coverage did not have a one-to-one relationship to the realities of any of the issues." While the media and public agendas were strongly linked, both had an arm's-length relationship with the historical trends of the decade.

Similar disconnects between 'the world outside' and the agendas of the media and the public have been found over the years for a wide variety of issues. From 1970 to 1990, the public responded to the increasing coverage of environmental problems in the face of decreasing air and water pollution (Ader, 1995). In the 1970s, public concern was aroused by news reports about the availability of petroleum in Germany when there was no real evidence of any shortage (Kepplinger and Roth, 1979). The salience of crime as an issue appears to be particularly susceptible to news coverage. Gordon and Heath (1981) found significant differences in concern about crime in Chicago, Philadelphia, and San Francisco between readers of newspapers with flamboyant crime coverage vs newspapers with conservative crime coverage. In the 1990s there was a similar public response in Texas to an increase in news coverage of crime during a time when there was a decreasing trend in actual crime (Ghanem, 1996). More recently, Gross and Aday (2003) found that exposure to local TV news with its heavy crime coverage was the major predictor of naming crime as an important issue in Washington, DC.

The public's response in all these situations is reminiscent of the phenomenon of 'alarmed discovery,' the initial stage of public response to a new issue on the agenda that is described

in Downs's (1972) theory of the 'issue attention cycle.' The media's presentation of the issues just discussed also can be characterized as 'alarmed discovery' because the news began to emphasize each of these issues at a time that nothing out of the ordinary was occurring in the real world. In effect, these were natural experiments in a real-world setting that yield compelling evidence of the agenda-setting impact of the news on the public.

These agenda-setting effects of the mass media occur worldwide, wherever there are reasonably open political and media systems. Under these circumstances, the public frequently turns to the news media for orientation on the major issues of the day, especially those issues beyond the ken of personal experience. Even in many cases where personal experience creates high salience for an issue, people turn to the media for additional information and perspective.

The concept in agenda-setting theory explaining this behavior is need for orientation (NFO), the cognitive equivalent of the physical science principle that nature abhors a vacuum. People are psychologically uncomfortable in unfamiliar situations, such as elections with a plethora of candidates and issues, and frequently turn to the media to satisfy their NFO (Weaver, 1977). This psychological concept, which is defined in terms of relevance and uncertainty, explains, for example, the strong agenda-setting effects found in 1968 among Chapel Hill undecided voters. Obviously, both relevance and uncertainty were high for these voters, the condition defining the highest level of NFO.

Matthes' (2006) recent reconceptualization of the measurement of NFO takes account of new developments in agenda-setting theory, particularly, attribute agenda setting, and expands the measurement to three dimensions: the NFO toward issues, toward facts, and toward journalistic evaluations. Chernov et al.'s (2011) experimental study found that both the traditional and new Matthes' NFO scales are reliable tools for predicting first-level agenda-setting effects, and that they are significantly correlated with each other. The traditional NFO scale performs better than the new NFO scale when predicting first-level agenda-setting effects. However, when only the first subdimension of the new NFO scale is used (i.e., NFO toward issues), both the traditional and new scales perform about equally.

With increased levels of media use, there is also increased agreement about the most important issues of the day among disparate demographic groups, such as men and women or those with high and low education. These patterns of social consensus have been found in Spain, Taiwan, and the USA (McCombs, 2014). Consensus also is facilitated by the limited capacity of the aggregate public agenda. Typically, no more than three to five issues are individually able to garner a constituency of 10% or more of the public who regard that single issue as the most important issue of the day, and the public agenda is best characterized as a zero-sum game (McCombs and Bell, 1996).

Sources of the Media Agenda

Although the majority of empirical research on agenda setting has examined the relationship between the media agenda and the public agenda, scholars also have asked "Who sets the media agenda?" Influences shaping the media agenda range from the external activities of major news sources to the internal dynamics of the media system (Dearing and Rogers, 1996; McCombs, 2014). Examination of the *New York Times* and *Washington Post* across a 20-year period found that nearly half of the news stories were based substantially on press releases and other direct inputs by news sources, such as press conferences and background briefings. News coverage of Louisiana government agencies was substantially based on information provided by their public information officers to the state's major newspapers. Across an 8-week period the correspondence between the agenda originating with the press information offices and all news stories about those agencies was +0.57.

Political campaigns make a concerted effort to influence the news agenda. In the 1993 British general election, a series of comparisons between the three major parties' agendas and seven news media, both newspapers and television, found a median correlation of +0.70. American political parties do not fare as well at the national level. A comparison of television news coverage during the 1996 New Hampshire Presidential primary, the inaugural primary in the lengthy US election year, with the candidates' speeches found only a moderate correspondence (+0.40) in their agendas. However, at the local level, in an election for Governor of Texas the combined agendas of the Democrat and Republican candidates shaped the issue agenda of both the local newspaper (+0.64) and the local television stations (+0.52) in the state capital. The Texas election also reflected intermedia agenda setting, the influence that one news medium has on another. In Austin, the correspondence between the local newspaper agenda and subsequent television news coverage of public issues was +0.73. A similar comparison in Pamplona, Spain, of two local newspapers with local television news found correlations of +0.66 and +0.70. In the USA, the *New York Times* is regarded as a major agenda-setter among the news media. A case study of the drug issue during the 1980s found that the *New York Times* influenced subsequent coverage by the national television networks, news magazines, and major regional newspapers.

Consequences of Agenda Setting

The agenda-setting role of the media has consequences beyond the focusing of public attention. These consequences encompass both attitudes and opinions and observable behavior. In terms of attitudes and opinions, it is important to distinguish two aspects, first the strength of opinion, beginning with the fundamental point of whether an opinion even exists. Strength of opinion also distinguishes between weakly and strongly held opinions regardless of whether those opinions are positive or negative. Second is the widely measured direction of opinion, whether some object or attribute is regarded in a positive or negative light.

To begin with the strength of opinion, there is a fundamental link between the first level of agenda setting, the transfer of object salience from the media agenda to the public agenda, and the formation of opinions by members of the public. For example, Kiousis and McCombs (2004) found a strong

relationship (+0.81) between the pattern of news coverage during the 1996 presidential election and the percentage of persons who held an opinion about each of 11 political figures. The greater the amount of news coverage, the greater the salience of that person among the public and the greater the likelihood of having an opinion about them. A strong relationship also was found between the pattern of news coverage and the strength of these opinions. Comparisons of the frequencies of presidential campaign stories mentioned in the *New York Times* and three network news broadcasts with a time series from the 2004 National Annenberg Election Study also found that increases in media coverage of the election were negatively related to the refusal rate in surveys about the election (Stroud and Kenski, 2001).

Turning to the direction of opinions, positive opinions during 1992 and 1993 about the overall performance in office by Hong Kong's last British Governor were significantly primed by the pattern of news coverage on his proposals to broaden public participation in local elections. Exposure to this news coverage significantly increased the importance of these proposals in Hong Kong residents' overall approval of the Governor's performance. By calling attention to some matters while ignoring others, the news media influence the criteria by which public officials subsequently are judged (Iyengar and Kinder, 1987). This process of priming is a major consequence of first-level agenda-setting effects, a process in which the salience of an issue among the public becomes a significant factor in opinions about a public figure associated with that issue. Priming effects on opinions about the overall performance of the president of the United States have been found for many presidents on a wide variety of issues. In short, there is a major link between the first level of agenda setting, the transfer of issue salience from the media agenda to the public agenda, and the direction of opinions expressed by members of the public.

At the second level of agenda setting, the tone of news reports and their attribute agenda-setting effects on the public are also related to the direction of opinions expressed by members of the public (Fishbein and Ajzen, 2010). In Germany, shifts in the tone of news stories about Helmut Kohl preceded shifts in public opinion from 1975 to 1984 (Kepplinger et al., 1989). Daily observations during the final 3 months of the 1992 and 1996 US Presidential campaigns found that the positive and negative tone of television news about key campaign events influenced voters' opinions about the candidates (Shaw, 1999). The pattern of negative headlines about the US economy over a 13-year period influenced both subsequent measures of consumer sentiment and major statistical measures of the actual economy (Blood and Phillips, 1997).

Conclusion

The history of agenda-setting theory in the decades since the 1968 Chapel Hill study is rich and productive. In particular, the theoretical expansion to three levels of effects and the consequences of these effects for attitudes and opinions require the revision of Bernard Cohen's (1963) seminal observation that the media may not tell us what to think, but are stunningly successful in telling us what to think about. His distinction between the affective and cognitive effects of the media was an important precedent for research on first-level agenda setting. In turn, the expansion to a second level of effects, attribute agenda setting, and its consequences reinvigorated the consideration of media effects on attitudes and opinions. This expanding perspective, now joined by a third level of effects, also is a rebuttal of the criticism that agenda setting has focused narrowly on the initial stages of the communication and public opinion process.

Agenda-setting theory details the range of effects on the public that result from the news media's inadvertent focus on a small number of topics and their attributes. To the extent that the news agenda is set by social forces external to the news media, the role of news institutions is important, but neutral, as a transmission belt. To the extent that the news media exercise autonomy in defining the public's news diet, they are in themselves a powerful social force.

Abstract

It is not until recent decades that an extensive empirical research tradition has emerged in relation to policy agenda-setting. The starting point for this research has been the agenda-setting models of Kingdon as well as Baumgartner and Jones. The concepts and ideas of these two models have led to empirical investigations of many aspects of policy agenda-setting. In recent years, the policy agenda-setting literature has developed a broader focus which includes questions relating to the traditional comparative public policy literature like the role of political parties.

The agenda-setting tradition is one of the most established research traditions in public policy studies (*see* Public Policy). It is often referred to as 'policy agenda-setting theory' (Baumgartner et al., 2006), a description that distinguishes it from other agenda-setting traditions, which do not directly study public policy, for instance, studies of how the media influence the public agenda or studies how control of the formal agenda provides opportunities to influence the outcome of voting processes in parliament (*see* Agendas: Political).

The core claim of the policy agenda-setting tradition is that changes in attention generate policy changes. If we want to understand why and how some policy changes – and why it does not – it is crucial to study what issues or policy questions the decision makers pay attention to and what makes them change their attention. A fundamental idea of the tradition is that attention is a scarce commodity in politics and the existence of problems and solutions does not by itself generate decisions. You need the scarce thing called the actors' attention.

The following describes how this very general understanding of policy making has been unfolded into empirical research. We outline the intellectual origins of the tradition and the research tradition with focus on the two books that have shaped it: John Kingdon's (1984, 1995) *Agendas, Alternatives and Public Policies*, and Frank R. Baumgartner and Bryan D. Jones' (1993, 2009) *Agendas and Instability in American Politics*. (Both have appeared in several editions. The new editions are primarily updates of the empirical material from the first editions. The 1995 version of John Kingdon's book and the 2009 version of Baumgartner and Jones' book are used here.) We also outline some of the findings from a number of recent comparative studies which show how an understanding of agenda-setting dynamics is crucial for explaining comparative differences in public policy.

The Roots of Policy Agenda-Setting Research

The intellectual roots of the policy agenda-setting tradition are two seminal pieces in political science. One is Bachrach and Baratz's article on the *Two Faces of Power* (1962), where the second face of power points to the crucial role of agendas (*see* Power). The other and probably the most important one is Schattschneider's (1960) *The Semisovereign People*. Many of the central insights from the book like: 'Organization is the mobilization of bias,' 'The definition of alternatives is the supreme instrument of power' and 'A conflict is likely to change profoundly as it becomes political' are core insights in policy agenda-setting research today. Or, put simply, current research within the policy agenda-setting tradition can be considered attempts to turn Schattschneider's ideas into empirical research.

Though the intellectual roots of the policy agenda-setting tradition are 50 years old, policy agenda-setting research as an empirical research tradition did not take off until the 1970s and has not really flourished until the last 15–20 years. Part of the reason is probably that the founding works of the tradition, i.e., Schattschneider and Bachrach/Baratz, focused more on presenting the importance of agenda-setting as a critique of the pluralist view of the openness of the political system. Thus, the starting point for the tradition was focused on highlighting the importance of keeping issues away from the agenda rather than – empirically – researching the issues that did receive political attention.

Studies of Policy Agenda-Setting

The First Studies

The first example of more 'positive' and empirically oriented policy agenda-setting research was Cobb and Elder's book (1972, 1983) *Participation in American Politics*. (The book was published in a second edition in 1983. References are made to the second edition.) Besides being the first book-size example of empirical studies of agenda-setting, the book raised at least two theoretical issues that have been central in the tradition since. One is the question 'What is an agenda?' In the policy agenda-setting tradition, the political agenda is broadly understood as the set of issues that are debated and considered for decision in a political system at a given time (Baumgartner, 2001: p. 288). Though broadly agreed on, such a definition is too general as guidance for empirical research. Thus Cobb and Elder (1983: pp. 14–16) introduced a distinction between a systemic and an institutional agenda. The systemic agenda is issues discussed in society, whereas the institutional agenda is the agenda of a particular political institution. The distinction opened a question about the relationship between the issues debated in society and in the institutions in the political system

as well as a discussion about the relationship between the agendas of different institutions in the political system.

The other theoretical question was the importance of issue characteristics. In the policy agenda-setting tradition issues are mostly understood as relatively broad policy issues like energy, the economy, health, or education, but sometimes also more narrowly as particular policy questions like abortion, nuclear power, or inflation. No matter how broadly issues are defined, their policy content varies enormously. From a policy perspective, the economy or inflation is very different from transportation or railways. By focusing on issue characteristics like technical complexity and the size of the affected public, Cobb and Elder (1983: pp. 94–109) offered the first attempt to theorize how agenda-setting processes were affected by an issue's characteristics. Though Cobb and Elder's book contained many questions for future agenda-setting research, few were actually taken up.

Simultaneously with Cobb and Elder's book, Downs (1972) published the article 'Up and down with ecology. The issue attention cycle.' The article has been influential with its analysis of the public or systemic agenda and how attention to a particular issue – in this case the environment – may suddenly be triggered, but disappear again as people realize that problems like the environment cannot be solved. The idea of an issue attention cycle thus highlights how attention is very volatile if it is not in some way institutionalized as it rarely is when we study the public or systemic agenda.

Kingdon's Model of Agenda-Setting

The next major study is Kingdon's seminal book, *Agendas, Alternatives and Public Policies*, first published in 1984, which presents a theory or a framework for understanding how attention affects political decision making that is still central within the policy agenda-setting tradition. A useful starting point for presenting Kingdon's agenda-setting model is his distinction between what he labels the governmental agenda and the decision-making agenda (1995: pp. 3–4). The governmental agenda is basically the issues that government officials and the actors surrounding them (experts, lobbyist, politicians, and journalists) pay attention to, whereas the decision-making agenda is the issues on the governmental agenda that are actually up for decision. To put it simply, Kingdon's model of agenda-setting can be considered a model of how issues move from the governmental agenda to the decision agenda or what it takes to move issues from just being considered by political actors toward actually being decided on. This also implies that Kingdon when compared with for instance Cobb and Elder focuses on a subsequent aspect of the policy making process. The question of how the governmental agenda relates to the systemic agenda is not Kingdon's central focus. Questions relating to the systemic agenda are mainly considered when they are important for understanding the relationship between the governmental agenda and the decision-making agenda. Kingdon's model of agenda-setting also draws extensively on organizational and decision-making theory, especially the garbage can model (1995: pp. 84–86).

Key concepts in Kingdon's model are the three streams of problems, alternatives and politics. Problems (1995: pp. 90–115) are basically societal problems. Alternatives (1995: pp. 116–144), or 'the policy primeval soup,' consist of the different policy solutions that actors within the policy communities surrounding most issues are trying to promote. Finally, the politics stream consists of political factors like the public mood, election results, and changes of administration – or government outside the US context (1995: pp. 145–164). According to Kingdon, the streams are normally not connected. Thus the mere existence of problems and alternatives, i.e., solutions, does not move issues from the governmental to the decision-making agenda, nor does the existence of politics besides problems and alternatives. Further, there is no logical connection between the three streams. For instance, actors in the alternatives stream may be actively looking for problems with which to connect their preferred alternatives.

The streams are connected by policy windows (Kingdon, 1995: pp. 165–195), which may appear in the problem stream or the political stream. In the problem stream, focusing events – unpredictable events like earthquakes or terrorist attacks – may open policy windows, but policy windows that open in the problems stream are not necessarily unpredictable. Measuring societal conditions is an important aspect of defining them as political problems and the release of new measures, for instance unemployment statistics, constitutes an often predictable policy window. In the political stream, windows may open both predictably and unpredictably as well. A change of administration is predictable, but other aspects like the retreat of a minister and the appointment of a new one can be very unpredictable. Policy windows rarely open from the alternatives stream. New alternatives of course emerge, but that does not in itself open a policy window. Rather, new alternatives emerge in the policy primeval soup and then have to wait for a policy window to open where they might be connected with a problem. The coupling of the independent stream is not an automatic process even when a policy window has opened. The coupling of the three streams takes a 'policy entrepreneur' (pp. 172–183) who can use a political platform to couple the streams and thus move issues from the governmental to the decision-making agenda.

As Mucciaroni (2012) has pointed out, Kingdon's model is widely cited, but rarely directly tested and used as foundation for systematic empirical research. This may be an indication of the model's weaknesses. A frequent critique of Kingdon is that the model portrays the policy process as basically unpredictable, which of course makes it difficult to use it as a basis for predicting policy decisions. Kingdon's model clearly stresses the unpredictability of the agenda-setting process. No actor controls the process. However, Kingdon also points to many predictable aspects of the process. Policy windows can often be predicted by actors and certain actors are much more likely to be successful policy entrepreneurs than others. For instance, the US president has a privileged position (1995: pp. 23–26). Kingdon has also been central in developing a literature on focusing events (cf Birkland and DeYoung, 2012). That being said, the strength of his model is that it describes *when and how* rather than *why* issues move from the government agenda to the decision-making agenda.

Baumgartner and Jones' Model of Agenda-Setting

Kingdon's model of agenda-setting is an important part of the intellectual foundation of Baumgartner and Jones' work on agenda-setting, which has been pivotal in the development of the policy agenda-setting tradition over the past 20 years. Compared to Kingdon's agenda-setting model, Baumgartner and Jones' work initiated by the 1993 book has a somewhat different focus. Kingdon's model focused on how issues move onto the decision-making agenda during the short periods when policy windows open. Baumgartner and Jones' work focuses on long-term patterns of attention to policy issues and its effect on policy making. Whereas Kingdon – and Cobb and Elder – based their agenda-setting models on case studies, Baumgartner and Jones base their work on systematic long-term – often decades – tracking of attention to particular issues on the entire agenda. Likewise, attention was tracked on the systemic agenda – media attention and public opinion – and on institutional agendas like Congress, the Presidency, and the Supreme Court; see www.policyagendas.org.

The long-term perspective is a central feature of Baumgartner and Jones' work because it has been the foundation of the punctuated equilibrium model. The core idea of this model is that attention and public policy are characterized by long periods of stability and short periods of dramatic change. Such a pattern can only be observed when attention or policy is tracked over long periods. To understand what lies behind the punctuated equilibrium pattern, Baumgartner and Jones (1993) have developed an agenda-setting model that explains both stability and change. Stability or equilibrium is generated by the existence of what Baumgartner and Jones describe as 'policy monopolies' (2009: pp. 6–12) (*see* Issue Networks: Iron Triangles, Subgovernments, Policy Communities, Policy Networks). Such monopolies will develop around policy issues like nuclear power or tobacco. They contain both a venue like a congressional committee where actors interact, and a 'policy image' or a shared understanding of the particular policy problem. A policy image consists of both a causal understanding of the policy problem and a positive or negative view of it (pp. 25–38). One example is nuclear power in the US, which for a long time enjoyed a positive policy image. Nuclear power was seen a clean and efficient way of solving energy problems; it was linked to a causal understanding that nuclear power was safe and without major negative side effects like waste (Baumgartner and Jones, 2009: pp. 60–82).

Policy monopolies – consisting of venues and policy images – generate stability or equilibrium. If new information – for instance information about nuclear waste problems – challenges the policy image, the policy monopoly will able to ignore or diffuse the information. Such 'negative feedback mechanisms' ensure a policy monopoly long-term stability. However, nothing lasts forever and a central point in Baumgartner and Jones' agenda-setting model is that equilibriums are always 'local.' The political system in general is never in equilibrium, which implies that it is the interaction with the surrounding political system that is potentially destabilizing for a policy monopoly. There are always actors in the political system surrounding a policy monopoly who want to destabilize it, and one option is to use focusing events.

Such a 'Schattschneider mobilization' where attention to a policy issue is expanded beyond an existing policy monopoly may also be related to what Baumgartner and Jones (2009: pp. 86–102) label 'venue shopping.' A policy monopoly is linked to a particular venue and generating attention in another venue is a way to challenge the monopoly. The policy monopoly surrounding US tobacco policy – which was based on tobacco as an exportable agricultural product – was also linked to the agricultural committees in Congress. This monopoly has been overthrown by a process that started at the US state level. States like California had no interest in tobacco as an agricultural product, but had to bear the health care costs of smoking. US states thus began to regulate smoking and took the issue to the courts in order to reclaim health care costs. This expanded the tobacco issue to the broader political system and led to the breakdown of the original tobacco monopoly (2009: pp. 264–281).

Policy monopolies thus create local equilibriums, which may last long, but in the long run they will not stay isolated from the surrounding political system and may thus be overthrown. According to Baumgartner and Jones such periods are characterized by positive feedback processes where challenges to monopolies become self-reinforcing and policy monopolies that have existed for a long time may quickly disappear. Baumgartner and Jones call these short periods of changes 'punctuations.'

The idea of policy monopolies raises a number of questions; for example, what happens when new policy issues emerge, i.e., when there is prior policy monopoly? Policy monopolies do not emerge automatically, but are generated by what Baumgartner and Jones label a 'Downsian mobilization,' referring to Downs' analysis of the emergence of the environment on the systemic agenda. Downs' issue attention cycle implied that attention to issues disappears again. However, periods of intense attention to an issue leaves behind policy monopolies as actors are able to institutionalize their preferred policy image linked to certain policy venues. Periods of sparks in attention to new issues thus have long-term implications.

Baumgartner and Jones' work as first presented in the 1993 book has been pivotal in the flourishing of the policy agenda-setting tradition during the last decades. The most direct application of Baumgartner and Jones' (1993) book is testing the idea of punctuated equilibrium through studies of the distribution of changes in both attention and budgets. Punctuated equilibrium entails the idea of either stability or few dramatic changes, but few gradual changes. If we study the distribution of changes, we should thus see a picture of many very small changes, i.e., stability, and a few substantial changes. This distribution can be compared with a normal distribution and we can test whether it is leptokurtic, i.e., has a higher peak and more slender shoulders than a normal distribution. Changes in attention and budgets have been found to exhibit this pattern across different political systems (Baumgartner et al., 2009; Jones et al., 2009), but the pattern has also been found to be more pronounced the further we move down the policy cycle (*see* Policy Cycle). Policy decisions – budgets – are more leptokurtic than inputs to the political process like elections or media attention, which are closer to a normal distribution. The universal finding of punctuated equilibrium of course raises the question of what can explain it. Here Jones and Baumgartner (2005) point to the idea of friction in terms of information processing at both the individual level and the institutional level. Individuals and institutions tend to either over- or underattend problems.

Agenda-Setting and Comparative Public Policy

The work of Baumgartner and Jones has shaped the policy agenda-setting tradition fundamentally. In recent years, the tradition has thus been characterized by a 'comparative turn' based on the establishment of major datasets on attention in a number of countries similar to one developed by Baumgartner and Jones on the US, see www.comparativeagendas.info.

One the one hand, the development of these datasets have broadened the scope of policy agenda-setting theory beyond public policy to traditional comparative politics questions about party competition, federalism, coalition government, and the functioning of political systems (Green-Pedersen and Walgrave, 2014). One the other hand, the development of these comparative datasets has also moved policy agenda-setting literature closer to more traditional comparative public policy literature. In terms of interacting with comparative public policy literature, the policy agenda-setting tradition has traditionally been limited by its very strong US focus. The work of Kingdon and Baumgartner and Jones has only been based on studies of US policy making. With the comparative expansion of the policy agenda-setting tradition, the empirical foundation for interacting with the comparative public policy literature exists and there are a number of examples of this.

One example is Engeli et al.'s (2013) study of cross-national differences in policy permissiveness with regard to morality issues (abortion, euthanasia, stem cell research, etc.). The article argues that to understand such comparative differences, we must first understand whether the issues are politicized, i.e., are part of party competition. Whether or not morality issues are politicized can again be explained by whether or not there is a preexisting conflict in the party system between confessional and secular political parties (*see* Church and State). In the affirmative, morality issues are seen as yet another example of this conflict, which brings it into party competition. In countries where morality issues are politicized, permissive policy decisions are passed by secular governments, whereas confessional – often Christian Democratic – governments try to delay permissive decisions. In countries where morality issues are not politicized due to the absence of a conflict between confessional and secular parties, which parties govern is not decisive for permissive policy decisions. These decisions are rather generated by policy entrepreneurs like individual MPs or interest groups who manage to push the issues to a decision, often without much attention or political resistance.

Another example is Green-Pedersen and Krogstrup (2008) study of attention and policy change in relation to immigration in Denmark and Sweden (*see* Immigration Policy). Both countries had liberal immigration policies in the 1980s, but from the 1990s and especially during the 2000s, Danish immigration policy became considerably more restrictive. The explanation for this should be found in the in differences in agenda-setting process and party competition in the two countries. In Denmark, the major right-wing parties, the Conservatives and the Liberals, increased their attention to the issue when in opposition from 1993 to 2001 supported by the radical right-wing Danish People's Party. This lead to increasing political attention to immigration and caused the Social Democratic led government to tighten immigration policy. After returning to government in 2001, the Liberals and Conservatives implemented the very restrictive immigration policy they had argued for when in opposition. In Sweden, the right-wing bloc has always been dominated by center-right parties and the major right-wing party, the Conservatives, have always been forced to cooperate toward the center rather than toward the radical right. Therefore, the party has never tried to make immigration a central issue on the political agenda in Sweden by advocating a restrictive immigration policy. Immigration has thus never been central on the political agenda in Sweden and the country has stayed with its liberal immigration policy.

These comparative turn within policy agenda-setting research has also implied that theoretical debates within the comparative public policy literature are engaged more directly like for instance the 'do politics matter' debate (*see* Ideological Constraint: History and Current Status of the Concept). Seeberg's (2013) study of law and order in Denmark for instance show that politics do not only matter for public policy in terms of the color of the government. The opposition may also, if it is successful in bringing issues high on the political agenda, cause the government to move policy in the opposite direction of what the government would have preferred. Increasing attention to law and order in Denmark generated by the right-wing opposition thus caused the Social Democratic led governments in the 1990s to implement policies like longer sentences, which the Social Democrats had before resisted.

A final example of the comparative turn draws more directly on the concept of venue shopping developed by Baumgartner and Jones (2009). Political institutions function not only as arenas or venues of decision making but also as venues of attention. Filing a court case or scheduling a hearing is a way to draw attention to an issue whether or not a decision is made. Further, no political arena or venue is neutral. Tobacco-related questions are treated differently in a health care committee compared to an agricultural committee; and a court is very different from a congressional committee or a parliament. This idea has especially inspired studies of the European Union, where its 'complex' institutional structure makes the idea of venue shopping applicable. Guiradon (2000) study of immigration policy in the European Union and Sheingate's (2000) comparative study of agricultural policy in the European Union and the US are examples of this.

Recent Trends in Policy Agenda-Setting Research

Politics in Western countries have over the last decades being characterized by such developments as increased mediatization and rising importance of issue voting. This has made the question of agenda-setting of increasing importance. Today, it is less given which issues should dominate the political agenda and how they should be framed. The increased use of communication strategies and communication experts by political actors is one sign of this.

For our understanding of public policy, this makes a theoretical understanding of policy agenda-setting of increased importance. Political attention is still scarce, so most policy decisions are likely to be made with relative limited political attention from a closely defined group of actors – what Baumgartner and Jones describe as 'subsystem politics.'

However, the chances of issues and the related policy decision being subject to macropolitical attention have increased substantially. The agenda-setting literature has shown that attention is both scarce and consequential. If issues are brought out of the sub-system context and into macropolitics, the policy processes and decisions are likely to change.

Despite its long tradition, the policy agenda-setting literature has only begun to develop a profound theoretical understanding of agenda-setting dynamics and many aspects needs much further investigation. One aspect that is particularly in need of this is the question of framing or issue definition. 'Policy images' are a key element in a policy monopoly and more broadly points to the central importance of how policy problems are defined or framed. Baumgartner and Jones (2009 [1993]) were influenced by Deborah Stone's (1988) seminal book *Policy Paradox and Political Reason*, which highlighted how policy problems can be defined or constructed differently in terms of 'causal stories' with very different implications for policy solutions. The most recent and extensive empirical example of the importance of 'causal stories' or framing is Baumgartner et al.'s study of framing of the death penalty in the US (2008). The study is an ideal example of how framing can be studied empirically as it traces the long-term evolution of the framing of the issue in the media. It is also an ideal example of how powerful a reframing of an issue can be. Whereas the death penalty was long seen and supported as a morally justified sentence in case of particularly brutal crimes, it was increasingly framed as a policy tool that often led to wrongful convictions with huge costs for society. DNA tests proved the innocence of convicted and sometimes executed prisoners and raised serious questions about the death penalty as a reliable policy instrument. Further, the costs of long trials with numerous appeals often followed by long periods on death row for convicts were linked to widespread skepticism toward government in the US. The death penalty was framed as yet another example of an expensive government that makes too many mistakes. Support has declined; the number of executions has dropped; and many states have abolished the death penalty. This development came about because the issue was reframed as yet another example of government failure – not because public belief in death penalty as morally justified changed. This study clearly demonstrates how consequential a reframing of a policy question can be, but it is also a unique example and many more of such studies are needed.

The importance of agenda-setting dynamics for democratic political system has been recognized for decades. However, developments like mediatization and increased importance of issue voting have made it increasingly important to study agenda-setting process. In recent years the agenda-setting tradition has gained momentum and started to engage more directly with research within both the comparatively public policy tradition like the 'do politics matter' question and political science more broadly. Thus as agenda-setting is becoming more important, the research tradition has broadened its theoretical platform and has expanded its empirical basis much beyond the US.

Abstract

The political agenda is the set of issues that are the subject of decision making and debate within a given political system at any one time. The concept of conflict expansion is key to the idea of agendas. Issues are typically handled in a routine manner within specialized policy subsystems until they emerge on the agenda. Issue-definition, or framing, plays a key role here, as do the roles of individual policy entrepreneurs, social movements, and political leaders. Studies of agenda setting have blossomed in the past 10 years as new data resources have become available.

The political agenda is the set of issues that are the subject of decision making and debate within a given political system at any one time. Cobb and Elder (1972), in the first book-length treatment of the political agenda, noted the difference between the systemic agenda, defined as the group of issues that were under discussion in society, and the institutional agenda, or the set of issues being discussed in a particular government institution. Since then, scholars have variously written about the public agenda, the media agenda, the legislative agenda, and any number of other agendas as they have focused on different political institutions. Studies of agenda setting have often focused on the question of issue definition, which has led scholars to note the importance of social movements, professional communities, and strategically minded politicians and policy entrepreneurs in affecting how we think about important social issues, and how these social issues become political issues in the first place. Whereas the questions of agenda setting were once taken for granted or ignored, the field today is home to a vibrant intellectual community with many studies being conducted each year. Newly available quantitative indicators of public attention, media coverage, and the like have encouraged larger-scale studies of the agenda-setting process.

The political agenda is the set of issues that are the subject of decision making and debate within a given political system at any one time. Significant research specifically on the topic of agenda setting, as opposed to decision making, dates mostly from the 1960s. Early studies of agenda setting were quite controversial because they were often presented as critiques of the pluralist studies of the 1950s and 1960s. Truman (1951) mostly ignored the issue of who set the agenda of political debate. Dahl (1956) discusses the matter in mentioning that ensuring that no group has control over the range of alternatives discussed within the political system is a requisite for democracy. In his study of New Haven he explicitly raises the question of agenda setting, noting that with a permeable political system virtually all significant issues would likely come to the attention of the elites. "Because of the ease with which the political stratum can be penetrated, whenever dissatisfaction builds up in some segment of the electorate party politicians will probably learn of the discontent and calculate whether it might be converted into a political issue with an electoral pay-off" (Dahl, 1961: p. 93). In Dahl's view, then, any issue with a significant potential following in the public would likely find an elite-level champion, though he also notes that issues with no large-scale electoral pay-off might never enter the agenda.

Conflict Expansion

E.E. Schattschneider (1960) focused attention on how political debates often grow from the conflict of two actors, the more disadvantaged of whom may have an incentive to 'socialize' the conflict to a broader political arena. Of course, the more advantaged disputant strives to 'privatize' the conflict. Schattschneider was one of the first to note that the composition of the political agenda was itself a fundamental part of the political process, and he was the first to give it a prominent role in his view of the political system. By around 1960, then, scholars had firmly noted the importance of the study of the political agenda as an important area of research.

After the critique of Schattschneider (1960), scholars were less willing to take the composition of the agenda for granted. Peter Bachrach and Morton Baratz (1962) provided one of the most telling critiques of pluralism when they noted that studies of decision-making, power, and influence were misleading. Their aptly titled article, 'The two faces of power,' noted that the 'first face' of power, the authority to choose between alternatives, may be less important than the 'second face' of power, the ability to control what alternatives are under discussion in the first place. Whereas Dahl and others saw this as a relatively open process, where any social group with a legitimate problem that could potentially be converted into votes in an election could gain access to the political agenda, others saw the process in a decidedly more negative light. Following Bachrach and Baratz, many scholars attempted to study not just governmental decision making, as the pluralists had done, but also nondecisions, or agenda control, as well. For example, Matthew Crenson (1971) noted that air pollution was rarely discussed in public or government in one city despite a very serious pollution problem. In another similar city with much less pollution, however, public and governmental leaders discussed it often and took steps to combat it. The reason behind the difference in the behavior between the two cities appeared to be the ability of powerful economic interests to control the agenda. John Gaventa (1980) followed this study with an analysis of poverty-stricken Appalachian towns and the 'quiescence' characterizing the demobilized populations there.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93003-4

These agenda theorists argued that power was most evident when objective conditions of suffering were not the subject of debate. Bachrach and Baratz (1962), Crenson (1971), and Gaventa (1980) raised important issues and directly challenged the relatively optimistic views of the pluralists but did not convince all, because of the difficulty of discerning exactly what would be a neutral political agenda. In other words, it was hard to know what findings would demonstrate elite control and what findings would demonstrate democratic openness; in this situation two scholars looking at the same findings could disagree forever (and they did; see Baumgartner and Leech, 1998: Chapter 3, for a discussion of these issues relating to the community power studies of the 1950s and 1960s; see also Polsby's (1980) treatment of these methodological issues). For example, Dahl (1961) had already noted that politicians might become aware of a grievance but see no electoral value in acting on it. While this was perhaps portrayed as reflecting the lack of gain, it could also have been because of an expected push-back or objection from those interests who might be harmed if action were taken. For Gaventa and Crenson, emphasis was on this former possibility: that the economically and socially powerful would, through their closer connections to those in power, effectively keep important issues – especially those affecting the distribution of wealth – from ever reaching the agenda for debate. Dahl saw the system as relatively open for those with a significant grievance; Gaventa and Crenson suggested that perhaps this was not so, or true only within certain bounds of acceptability.

The Development of a Literature

Roger Cobb and Charles Elder (1972), in the first book-length treatment of the political agenda, noted the difference between the systemic agenda, defined as the group of issues that were under discussion in society, and the institutional agenda, or the set of issues being discussed in a particular government institution (see also Cobb et al., 1976). Since then, scholars have variously written about the public agenda, the media agenda, the legislative agenda, and any number of other agendas as they have focused on different political institutions.

More recent studies of agenda setting have moved away from the concepts of nondecisions and power because of the difficulties inherent in designing rigorous research on the topic. Instead, scholars have focused on the rise and fall of issues in the public or institutional agendas and how decision making during high salience periods differs from the more routine decision making that takes place when an issue is low on an agenda. Jack Walker (1977) provided one of the first statistically based studies in the area with his analysis of the US Senate's agenda. He noted that issues often rose on the Senate's agenda following heightened levels of discussion within professional communities.

John Kingdon's (1984) treatment of the public agenda set the stage for much of our current understanding of where issues come from. He emphasized the separate sources of policy problems from the solutions that may be offered to them. Government programs, he noted, come about when a given solution is attached to a particular problem, and his analysis of health care and transportation policies in the USA showed just how unpredictable these couplings can be. Political actors' search for popular issues, windows of opportunity open and close, stochastic events such as natural disasters or airplane crashes momentarily focus public attention on an issue. The confluence of many unrelated factors, often serendipitous, helps explain why a given policy is adopted, according to his study. Kingdon's (1984) was the first major book-length study on the topic since Cobb and Elder's (1972), and it was based on hundreds of interviews with government and other policymakers in the 1970s and 1980s. (Polsby, 1984 also reached many of these conclusion in a book that appeared in the same year as Kingdon's.)

Frank Baumgartner and Bryan Jones (1993) provided the next major treatment of political agendas in their analysis of nine different policy areas over a 40-year period. Utilizing publicly available sources such as media indices and records of congressional hearings, they noted how particular issues rose and fell on the agenda over the entire post-World War II period. They developed a punctuated equilibrium model of policy change in which episodic periods of high agenda status typically were related to dramatic and long-lasting policy changes. During these high-salience periods, institutional procedures were often created or altered. The subsequent ebbing of the issue from the public agenda enabled the newly empowered political institutions and policymakers to settle into stable routines of behavior persisting for decades at a time. Agenda setting was related to dramatic changes, often upsetting long-standing routines of behavior and power by replacing them with new ones.

Policy Communities

The literature on agenda setting is difficult to read outside the context of the literature on policy communities, issue-networks, and the roles of specialized communities of policy experts. This literature, dating at least to the early work of Bentley (1908), focuses on the idea that public policies develop complicated and specialized communities of experts who may gain some degree of autonomy through their shared knowledge of a given policy domain. Because the government deals simultaneously with hundreds or thousands of different public policies, at any given time the vast majority of these issues are 'off the agenda' and when they are, this means that specialized communities of experts are operating with relatively little political or journalistic oversight. The literature on 'iron triangles,' 'whirlpools,' 'subgovernments,' 'policy communities,' and 'issue-networks' focused on the potential for such groups to gain substantial autonomy from the broader political system (see for example Lowi, 1964, 1969; Berry, 1989; Browne, 1998; Heinz et al., 1993; Peterson, 1993; this work also carried over into comparative politics – Hall, 1993; Heclo, 1974, 1978; international relations – see Haas, 1992; Sikkink and Keck, 1999). The question of interest and one of the key motivators, following from Schattschneider's analysis of conflict expansion, was what happens when one set of political values dominates among the experts but another obtains in the larger political arena. Influential analyses of the US Congress were also based on a discussion of the 'Giant Jigsaw Puzzle' which involves granting relatively

significant influence to 'policy specialists' serving on the various committees, knowing that these specialists might be 'high demanders' for the services – such as aid to farmers or support for the Defense Department – if they were allowed to seek their committee assignments based on such factors as heavy constituency reliance on the industry in question (see Shepsle, 1978). Agenda setting is also the analysis of the dynamics of the relations among experts and generalists in the political arena, and of the political ramifications of devolving power to experts in different policy domain each working in parallel but with little centralized oversight.

Issue Definition

Schattschneider brought our attention to the dynamics of conflict expansion but he did not explicate a theory of how conflict expanders ask for help. Issue definition and framing are the keys here. Studies of agenda setting have often focused on these questions because of this. Echoing a major theme in Baumgartner and Jones (1993), David Rochefort and Roger Cobb (1994) brought together a number of essays showing how public understanding and media discussion of a given issue can change over time, often quite dramatically. Deborah Stone (1988) also discussed this in her analysis of 'causal stories.' Policy entrepreneurs frame issues by explaining the causes of a given problem with a narrative justifying a particular governmental response. Book-length studies of the issues of child abuse (Nelson, 1984), pesticides (Bosso, 1987), health care reform (Hacker, 1997), and various natural and human-made disasters (Birkland, 1997) have shown the impact of changing issue definitions and of focusing events in pushing an issue on to the public agenda. Roger Cobb and Marc Howard Ross (1997) brought together a series of essays on the rarely studied topic of 'agenda denial,' whereby political actors keep threatening issues off the agenda.

William Riker (1986, 1988, 1993, 1996) showed the importance of two related issues: the ability of strategically minded politicians to alter the terms of debate by skillfully manipulating issue definitions, and the power of formal agenda control. A voluminous literature in formal and game theory suggests that the controller of a formal agenda can affect the outcomes in a voting situation by altering the order in which alternatives are considered. Riker used game theory to illustrate how formal agenda control can affect such things as votes in a parliamentary setting, and case studies and historical illustrations to show how political leadership could be even more powerful through the means of altering issue definitions. Political leaders can utilize a combination of formal agenda control and informal debating skills to achieve their ends, according to Riker.

Social Movements and the Media

A number of scholars have noted that social movements have often successfully brought new issues onto the public agenda. Thomas Rochon's (1998) analysis of the peace movement in various Western countries fits in this tradition, as does the work of Douglas McAdam (1988), whose study of the Mississippi Freedom Summer documented the success of civil rights activists in putting the issue of racial equality on the national political agenda during the mid-1960s.

Studies of the media agenda have been legion, largely following from the early work of Max McCombs and Donald Shaw (1972); for a review of this literature, see Rogers and Dearing (1988). Bernard Cohen (1963) noted famously that while the media cannot tell the public what to think, they can have a great impact on what the public think about. Within political science, several authors have picked up on the issue of media effects on public opinion (Iyengar, 1991; Iyengar and Kinder, 1987). James Stimson (1991) noted the changes in a broadly measured national mood based on public opinion surveys; John Kingdon (1984) also put considerable emphasis on the national mood in his study of agenda setting in government. As policymakers consider what issues to spend their time on, Kingdon (1984) noted they often make reference to the idea of a national mood.

Studies of the political agenda have been remarkable in political science for their integrative character: rather than focusing on any particular institution of government, scholars have traced the sources of agenda setting in the public, in the roles of interest groups and social movements, by noting the roles of policy entrepreneurs, and by looking at the government in very broad terms. Of course this does not mean that political leaders play an insignificant role. From the work of Richard Neustadt (1960) onwards students of the US Presidency have noted the need for presidents to focus their energy on a few issues (see Light, 1982; for a similar study of congressional leadership see Bader, 1996). Studies of the Supreme Court have noted the extremely tight control that the Court maintains over its agenda, as well as the characteristics of the cases that it is most likely to take. The Court, of course, is unusual among political institutions in that its agenda is reactive rather than proactive. Congress or the President can reach out to discuss whatever issues appeal to them; the Court can only choose from the issues that are presented for its decision (see Perry, 1984; Caldeira and Wright, 1988).

Recent Extensions

Agenda-setting studies have been strongly affected by the creation of the US-based Policy Agendas Project (www.policyagendas.org) which makes available comprehensive databases of government actions from 1947 through the present. Studies using these datasets have allowed new types of policy analysis. For example, Jones and Baumgartner's *Politics of Attention* (2005) shifted focus from the political agenda per se to the limits of human cognition, arguing that institutional designs capable of impressive serial processing (see Simon, 1985) were nonetheless constrained by a 'bottleneck of attention' reflected in the limited agenda of the centralized political leadership (see also Jones, 1994, 2001). This, in turn, has led to a growing literature on budgetary distributions which has shown in every case that budget changes over time are characterized by a distribution with a strong tendency toward recreating the status quo (e.g., many very small changes) at the same time as they have very

'fat tails' (e.g., many high-percentage changes; these findings have been replicated for the US federal budget, in states and municipalities, school districts, and in a number of western countries (see Breunig and Koski, 2006; Breunig et al., 2010; John and Margetts, 2003; Jones et al., 2009; Jordan, 2003; Mortensen, 2005; Robinson, 2004)). These studies have also led to analyses of how institutional decision costs (e.g., 'friction') relate to the efficiency of the resulting decisions (Baumgartner et al., 2009; Jones et al., 2003).

Studies based on the quantitative agendas approach have also led to replications in many other countries where scholars have replicated the methodology of the US agendas project. While these are too numerous and diverse to enumerate here, the comparative agendas project website (www.comparativeagendas.info) and several publications give an overview (see Green-Pedersen and Walgrave, 2014) or single country focus (see John et al., 2013).

Conclusion

In sharp contrast to two generations ago, research on political agendas is vibrant and promising today. Though much of the work has been done within the context of US politics, comparative studies have become more common (see Hogwood, 1987; Baumgartner, 1989; Reich, 1991; Zahariadis, 1995; John, 1998). New sources of quantitative data on public attitudes, government archives, and media coverage promise more systematic studies covering a greater range of issues over a longer time period than was typically possible in the past. Studies of political agendas are now firmly established as an important part of the field of political science now some 50 years after the concept was first discussed.

Abstract

Agent-based models (ABMs) have become an important simulation tool for understanding certain categories of complex phenomena. They are widely used in epidemiology, ecology, transportation research, social networks, and other applications in which the global behavior is determined by local behavior (which is usually quite simple, and can be represented through a concise set of rules). However, unlike many other models, such as linear regression, the statistical issues associated with ABMs are largely undeveloped.

Introduction

Agent-based models (ABMs) are a simulation strategy that is especially useful when the phenomenon of interest is complex, not continuously dependent on underlying parameters, and can be described in terms of local actions. In Europe and in some academic disciplines, such as ecology, ABMs are commonly referred to as 'individual-based models.'

Popular applications of ABMs include:

- Weather forecasting, in which each agent is a cubic kilometer of atmosphere, and the local interactions are the exchange of pressure, temperature, and moisture (cannot find this one).
- Auctions, as in Yahoo! or Google, to determine which ads are shown to users (Charles et al., 2013).
- Traffic flow models, as in TRANSIMS, where agents (drivers) space themselves according to the actions of other nearby drivers, and make route choices based on congestion avoidance (Smith et al., 1995).
- Genetic algorithms, in which the agents are primitive algorithms, which interact so as to evolve more successful algorithms (Chatterjee et al., 1996).

ABMs are commonly used in epidemiology, economics, social networks, and many other fields. Often the primary question of interest concerns emergent behavior generated by the cumulative actions of distinct entities, each making choices that satisfy its own requirements.

As a simple example to fix the basic concepts, assume that a safety engineer wants to determine how long it would take to evacuate an office building. The ABM approach would start with a virtual representation of the building, with the rooms and doors and stairs, and then place a typical number of people (agents) at random within the building. Each agent would follow two rules: (1) When the firebell rings, go to the nearest exit; and (2) If the exit is blocked, go to the closest exit that is unblocked. There would be additional constraints on how much crowding is possible in, for example, a stairwell or doorway. In this framework, the safety engineer might run the simulator 100 times, and create a histogram of how long was needed to complete the evacuation. One particularly attractive feature of the ABM approach is that the engineer can play 'what if?' scenarios, such as blocking certain stairwells or adding agents who act as fire marshals and direct the traffic. A second attractive feature is that the engineer can examine the rule set to see if it makes sense – perhaps something more complicated is needed, such as allowing agents who are away from their office to return and pick up their laptops before exiting.

This example indicates a number of features that are common to most ABMs. First, there is a 'geography' in which the agents operate. In this example, it was the virtual building; in TRANSIMS it is the road network; and with weather forecasting it is a three-dimensional grid of cubic kilometers. However, geography is not essential – the auction example and the genetic algorithms example do not require one.

Additionally, there are agents, which follow specific rules. The agents may be of multiple types, such as the employees and the fire marshals in the building evacuation example. Alternatively, the agents may be identical up to a prespecified parameter; for example, in virtual auctions different bidders respond to different keywords, have different amounts of money, and so forth, but all have the same objective.

The rule sets are the most critical common element. The rules are usually simple, but very flexible, and can be readily examined for plausibility. In particular, the rules may allow very unsmooth simulations; for example, in the building evacuation example, an agent may pick among separate exit paths.

Often, an ABM evolves over time, and there is interest in some ensemble behavior that is determined by the interaction of the agents. In the evacuation example, the ensemble behavior is how long it takes to empty the building, and this depends on crowding and the decisions of the agents in the building who only have local information about which exits are blocked. In the TRANSIMS example, the relevant behavior may be some measure of congestion, and in the weather forecasting application it may be temperature or rainfall prediction.

The following sections will elaborate on these issues. Section The History of ABMs traces the history of ABMs, with special emphasis on three influential applications. Section Limitations of ABMs lays out the research challenges in the ABM methodology, and points up some of the ways in which these are being addressed.

The History of ABMs

ABMs grew up with the era of modern computing. Their inception is rooted in cellular automata, a special case of ABMs

invented by John von Neumann and Stanislaw Ulam while pioneering the computing era at Los Alamos in the 1940s (Wolfram, 2002).

Cellular automata are ABMs in which the geography is a grid, and the grid points or the cells formed by the grid interact according to well-chosen rules. The most famous of these is Conway's Game of Life (Gardner, 1970), but the field is rich.

Stephen Wolfram's *A New Kind of Science* is an extensive survey of cellular automata, and argues that these represent a critical frontier for science.

Cellular automata have been generalized in many ways. In probability, interacting particle systems extend cellular automata to situations in which time is continuous rather than discrete and randomness plays a larger role (Liggett, 1985). But the main development has been increasingly rich characterizations of the cells and the actions that are taken; instead of cells in a space that are assigned colors according to some rule set, they have become agents, whose locations may change, rules may evolve, and which can respond adaptively to their environment.

The following subsections trace the historical growth in the sophistication of ABMs through three highly influential examples. Kauffman's model introduced agents that interact through a random network rather than a grid, and led to new insights in biology and new mathematical problems. Artificial societies created by Epstein and Axtell opened the door to a wide range of ABM applications in the social sciences, and the analysis of the spread of rabies in raccoon populations introduced the use of hierarchical statistical models in ABMs.

Kauffman's Random Networks

Stanley Kauffman wanted to understand how the same DNA could produce all of the different tissue types found in organisms. To study this, he used an ABM described in his seminal paper, 'Metabolic Stability and Epigenesis in Randomly Constructed Genetic Nets' (Kauffman, 1969).

In Kauffman's model, each agent is a gene. Each gene is either off or on, 0 or 1, depending upon the inputs it receives from other genes. Genes receive inputs from other genes, calculate a Boolean function, and send the result to other genes. In terms of the previous framework, the rule set is the Boolean function or functions, and the geography is the network through which inputs are received and outputs are transmitted.

In Kauffman's ABM, a large number (n) of agents are connected in a network at random, subject to the constraint that each agent must receive inputs from k agents (possibly including itself) and send output to k agents. Given its inputs, each agent uses a Boolean function to produce its binary output. Different agents may have different Boolean functions, and Kauffman assigned those functions to agents at random (excluding two degenerate functions, which always produce 0 or 1). The property of interest was the number of stable cycles that such a system could produce.

If a gene receives k inputs, then there are 2^k possible vectors of inputs (since each of the k inputs may be 0 or 1). And for any given vector of inputs, there are two possible outputs, 0 or 1. So the number of possible functions that map $\{0,1\}^k \rightarrow \{0,1\}$ is 2^{2^k}. Table 1 shows 3 of the 16 possible Boolean functions when $k = 2$.

Table 1 The first table corresponds to Boolean operator AND, the second is OR, and the last is tautology, one of the two degenerate operators that Kauffman excluded. The operator names derive from truth tables used in formal logic

Input		Output
0	0	0
0	1	0
1	0	0
1	1	1

Input		Output
0	0	0
0	1	1
1	1	1
1	0	1

Input		Output
0	0	1
0	1	1
1	0	1
1	1	1

Figure 1 shows how Kauffman's model enabled study of the number of stable cycles in a randomly connected Boolean network. The first panel shows five randomly connected agents (nodes). The agents are either OR or AND operators, as indicated. The second panel shows the transitions between states for the largest component; i.e., if the five agents are initialized as (0, 1, 0, 0, 1) (i.e., the value in the lowest corner of the panel), then the next state is (1, 0, 0, 1, 1), then (1, 0, 1, 1, 1), then (1, 1, 1, 1, 1). This last state is an absorbing state; if the system reaches that state, it does not leave that state. The last panel shows the three other components that are possible. If the system starts in the (0, 1, 0, 0, 0) state, then it evolves to the absorbing state (0, 0, 0, 0, 0). If it starts in the (0, 0, 1, 0, 1) state, it evolves to a stable cycle with three states: (1, 0, 0, 0, 0) going to (0, 0, 0, 1, 0) going to (0, 0, 0, 0, 1) which returns to (1, 0, 0, 0, 0), and so forth.

Epstein and Axtell's Artificial Societies

Epstein and Axtell (1996) brought the ABM perspective strongly into the field of social science. Specifically, they showed that simple rules could lead agents to display many of the complex behaviors found in human societies, including population dynamics, hunter-gatherer migration, division of labor, and a barter economy.

The Epstein and Axtell ABM was based on a planar lattice, which they called a 'sugarscape.' At each intersection of the lattice a resource, 'sugar,' grew at a constant rate. Initially, a fixed number of agents were placed randomly at the intersections of the lattice, with the rule that they were to consume sugar (at a constant rate greater than sugar's growth rate) until the supply was exhausted, and then move to the nearby lattice point and continue consuming. The result was that agents tended to move in large circles whose circumference matched the rate of growth of sugar, so that when the agent returned to its starting point, the sugar was fully replenished. This mirrors the migratory patterns of hunter-gatherer societies, in which phenology drives movement. Figure 2 shows one time point in a sugarscape simulation.

Next, Epstein and Axtell added gender and reproduction. When there was sufficient food and agents of opposite gender were on adjacent lattice intersections, they would have a child. This led to population pyramids, carrying capacity limits to growth, and many other features found in population dynamics. If the rules were extended so that families preferred to stay near each other, tribalism emerged.

Additional rules allowed pollution, diffusion of pollution, accumulation of wealth, the evolution of genetic traits, the spread of disease, specialized labor, cultural tags (memes) that could be shared or defended, trade, and combat. In all, 17 rules

Figure 1 This figure shows how the randomly connected Boolean network, under various initializations, transitions to different stable behaviors, where each stable behavior is an absorbing state or cycle. (a) A network of five agents (genes) in which each agent receives input from two agents and transmits its output to two agents. (b) The largest confluent of states. (c) The remaining three state confluents. Notice that two are, at their center, state cycles.

were sufficient to produce a rich range of social behavior. To illustrate these rules, consider three of them (taken verbatim from Epstein and Axtell, 1996):

1. *Sugarscape growback*: At each lattice position, sugar grows back at a rate of α per time interval up to the capacity of that position.
2. *Agent movement*: Look out as far as vision permits in each of the four lattice directions, north, south, east, and west:
   a. Considering only unoccupied lattice positions, find the nearest position producing maximum welfare;
   b. Move to the new position;
   c. Collect all the resources at that location.
3. Agent mating:
   a. Select a neighboring agent at random;
   b. If the neighboring agent is of the opposite sex *and* if both agents are fertile *and* at least one of the agents has an empty neighboring site *then* a newborn is produced by crossing over the parents' genetic and cultural characteristics;
   c. Repeat for all neighbors.

Note that the first rule includes a tunable parameter; there are many such cases in the full list; and this is common in ABMs in general.

The sugarscape rules are simple to program and easily interpretable in the context of the model. But they do not lend themselves to mathematical expression or analysis.

Rabies in Raccoons

Hooten and Wikle (2010) introduced Bayesian hierarchical models into ABM research. Their technique does not apply to all of the very wide range of ABM formulations, but it is useful for spatiotemporal processes with fairly simple structure.

Their motivating application is the spread of rabies in raccoon populations in Connecticut between 1991 and 1995. On a gridded map representing the townships in the state of Connecticut, they represented the presence or absence of rabies by a binary random variable whose distribution depended upon the states in the neighboring townships at the preceding time period, as well as covariates (which could also vary in time).

Figure 2 A snapshot of the Sugarscape model described in Epstein, J., Axtell, R., 1996. Growing Artificial Societies: Social Science from the Bottom up. Brookings Institution Press, MIT Press, Cambridge/Washington, DC. Agent locations reflect geographical variation in the rate of growth of 'sugar.' The image was captured from the NetLogo model described in Li, J., Wilensky, U., 2009. NetLogo Sugarscape 3 Wealth Distribution Model. Center for Connected Learning and Computer-Based Modeling, Northwestern University, Evanston, IL. http://ccl.northwestern.edu/netlogo/models/Sugarscape3WealthDistribution.

Let $\boldsymbol{u}_t = (u(1,t), u(2,t), \ldots, u(m,t))'$ denote the binary vector showing the presence or absence of rabies at time t for each of the m townships and let $\boldsymbol{X}_t = (\boldsymbol{x}(1,t), \boldsymbol{x}(2,t), \ldots, \boldsymbol{x}(m,t))$ denote a matrix of corresponding covariates, such as population density, adjacency to the Connecticut River, and so forth. Define the neighborhood for township i by N_i; this is a set of townships. Then the basic model for the spread of the disease is

$$u_{i,t} \big| u_{N_i,t-1} \sim \left[u_{i,t} \big| h\left(u_{N_i,t-1}, x_{N_i,t-1}\right) \right]$$

where $h(\cdot,\cdot)$ is a very general updating function, the subscript N_i indicates the townships relevant to the disease spread at township i (i.e., its neighboring townships), and the bracket notation indicates that the presence or absence of rabies is a random variable with parameters that depend on the conditioning within the bracket. The only substantive difference between this model and a Gaussian state space model is that the random variables need not be Gaussian (which generally precludes closed-form solution, putting this in the realm of ABM simulation).

This model is flexible, and enables disease spread to be anisotropic (i.e., directional, e.g., along the Connecticut River). It enables probabilistic statements about the posterior probability of disease in a particular township, but usually requires Markov chain Monte Carlo (cf Robert and Casella, 2004) to evaluate. It does not apply to all ABMs (e.g., genetic algorithms or the evacuation of a building), but when it does apply, it permits more explicitly statistical inference on the behavior of the ABM.

Limitations of ABMs

ABMs are popular and will be used for the foreseeable future. The primary reasons for this popularity are that they are relatively simple to code and straightforward to validate, at the least at a basic level. Not all problems are amenable to ABM representation, but for those that are, ABMs are generally easier to conceptualize and communicate than models based on complex stochastic processes or other mathematical representations.

Nonetheless, ABMs are problematic, because there is no robust theory of statistical inference. An ABM is a model, just as a linear regression is a model. Statisticians know how to fit linear models, how to assess fit, how to make predictions from linear models with quantified uncertainty, and so forth. But there is virtually no principled theory yet for ABMs.

Verification and Validation

Verification pertains to determining whether the code in an ABM is error-free. Validation asks whether the ABM is sufficiently faithful to reality. Verification lies outside the scope of this article, other than to acknowledge that it is a significant problem, especially in complex ABMs that may entail many thousands of lines of code.

Regarding validation, there are different approaches. Some of these are more rigorous than others, and some of these apply better to some situations than others (cf Louie and Carley, 2008). But none of these is fully satisfactory.

Physics-based validation is commonly used in the hard sciences. One builds a simulation that incorporates all of the physical laws and interactions that are appropriate, and then feels confident that their model is faithful to reality. This can work on smaller problems where all mechanisms are fully understood. Examples, where it is arguably successful, include planetary motions (cf Miller and Page, Section 6.6., 2007), flight simulators, and perhaps virtual mock-ups of semiconductor manufacturing processes. But it tends to break down as the stochasticity and complexity of the problem increase. Also, physics-based modeling often constructs the process in more detail that is actually required for reasonable fidelity, and thus takes a very long time to run.

A second approach might be termed intelligent design. This is the most common validation protocol, and is probably used in all but the most critical applications. Domain experts think through the simulation carefully, building in or approximating all the effects, which they think are substantial. Then they hope that they have been smart enough and wait to see if their results work well enough. Intelligent design can handle more complicated situations than the physics-based models, but it is not a true validation. The review process is more like a careful check of the thinking behind the model.

Face validity is a true validation protocol. The designer tests the ABM by using selected inputs to explore the output behavior. Often the selected inputs are chosen according to a statistical design, such as a Latin hypercube (cite), which increases efficiency greatly when the dimension of the input space is not too large. Alternatively, the designer can select values for the inputs that correspond to expected behaviors or regions in which predictive accuracy is especially important. Face validation is insufficient when the parameter space is large

and there are many interactions. But, to varying degrees, it is used for systems such as TRANSIMS and the battlefield simulations produced at the Defense Modeling and Simulation Office (Davis and Anderson, 2004).

A stronger validation protocol is based upon comparison to another, independently derived, model. This is not done often enough, but it has the potential to be a powerful tool. The advantages are that one can better explore the full range of model behavior. The disadvantage is that it often requires duplication of effort and a great deal of more development expense. But sometimes different scientific teams have developed different approaches to the same problem, as in the weather forecasting example, for which stochastic partial differential equation approximations are also used. In that case, comparison of the models can highlight the strengths and deficiencies of both.

The strongest form of validation occurs when one compares ABM outputs to the historical record for the phenomenon of interest. In principle, this is possible for weather forecasting, epidemic modeling, and TRANSIMS. However, all of these examples are noisy systems, so one expects divergence between the ABM prediction and the actual historical data. One must decide whether the error is unbiased and its variance matches the application of interest, and this requires a great deal of historical data and many runs of the ABM. Although comparison to real-world data is the strongest form of validation, it is still inadequate. One does not have confidence in the fidelity of the simulation in regimes that have not been previously observed, and this is often the context of greatest interest.

Inference

Given an arbitrary ABM, there is no clearly formulated inferential procedure (as is available, say, for a linear regression model). One would like to determine how to tune the parameters in an ABM to fit a given data set, or how to decide which covariates are actually important to the behavior of interest in the ABM.

There are two possible strategies for improving statistical inference in situations for which one cannot write out the likelihood function. The first is based upon emulators. These are Gaussian process approximations to complex systems, where Bayesian methods allow one to combine real-world data with multiple runs of the ABM to estimate tuning functions that provide the best possible fit, and to identify regions of the input space for which the emulator offers a poor approximation to the ABM. Emulators were proposed by Kennedy and O'Hagan (2001), and have been subsequently elaborated by many researchers.

The second possible strategy is Approximate Bayesian Computation (ABC). The method was conceptually proposed by Rubin (1984), but realized in its modern form by Tavaré et al. (1997). ABC starts with a prior over the parameter space of the ABM. It generates a realization of those parameters, runs the ABM, and produces a simulated data set. That data set is compared to real-world data; if it is close with respect some metric appropriate to the research domain, then the random parameters that generated the sample are accepted, and that point in the parameter space has increased posterior probability. The ABC process repeats until one has an estimate of posterior density function.

Both emulators and ABCs are ongoing areas of research, and their strengths and weaknesses, especially in the context of high-dimensional applications, are not fully understood. In particular, it is not known how to decide which of these is most useful in a particular ABM application.

Distances between Models

A third issue in the statistics of ABMs concerns the comparison of two models, when at least one of the models is an ABM. For example, consider the problem of estimating the spread of an epidemic. One person might build an ABM that included a geography based on a city network, where agents have rule sets that move them around the city, and when an infected agent meets an uninfected agent, there is a chance of transmitting the disease. But a second person might create a similar ABM, but with more and different detail, such as higher transmission rates in day care centers or periodic crowding such as church services or smaller time steps that allow more opportunity for people to meet. There is no clear strategy for deciding what degree of elaboration is needed, nor when one model is a proper subset of another. This is complicated by the fact that the input parameters for one model may be the same as, entirely different from, or partially overlapping the input sets for the other.

A similar issue arises when deciding between an ABM and a differential equation model. For example, again in the context of epidemiology, a mathematician might be tempted to use a Kermack–McKendrick model (Kermack and McKendrick, 1927), in which the change in the numbers of susceptibles (S), infected (I), and recovered (R) is described by a system of coupled differential equations:

$$\frac{\mathrm{d}S}{\mathrm{d}t} = -\beta SI \quad \frac{\mathrm{d}I}{\mathrm{d}t} = \beta SI - \gamma I \quad \frac{\mathrm{d}R}{\mathrm{d}t} = \gamma I$$

Qualitatively, the differential equations should produce similar dynamics to those obtained from an elaborate ABM. But there is no formal procedure for deciding how close these two models are, nor whether one is substantially better than the other in terms of the emergent behavior of interest. Bagni et al. (2002) discuss comparison of such epidemiolgical models in more detail.

Abstract

For over seven decades social psychological theories advanced understanding of aggressive behavior. The most recent major model – the General Aggression Model (GAM) – integrates prior theories, thereby encompassing the broadest range of aggressive phenomena. GAM is built on research about factors within a person that predispose them to aggression; factors from the environment that trigger aggression; and the underlying biological, neurocognitive, and psychological processes. This article summarizes historical and modern social psychological theories of aggression, key research methodologies and findings, and challenges of studying violence and aggression in society. It concludes by noting areas for future social psychological research of aggression.

Human aggression is a social behavior, and whilst it has been studied from many perspectives, it is theoretical models and empirical research from the field of social psychology that have provided the strongest framework from which to understand it. This article focuses on the contribution of social psychologists to the understanding of human aggression, providing first some key definitions, then major theories (both classic and contemporary) and a brief summary of social psychological approaches to the study of aggressive behavior. An overview of research findings is presented, including those describing factors within a person that increase the likelihood they will aggress, situational cues that can trigger aggression, internal psychological processes that underlie an instance of aggressive behavior, and processes that increase trait aggressiveness. We conclude by suggesting a 'risk factor' framework for understanding societal violence and noting directions for future research.

Definitions and Characteristics of Aggression

Definitions

There are three key issues with defining human aggression. First, it is hard to interpret research findings and theories about aggression without a clear definition. Historically, however, many different definitions have been used. As a result, many studies of aggressive behavior are hard to meaningfully compare. More recently, definitions of aggression among social psychologists have converged around the notion that aggression is any behavior enacted with the intention to harm another person who is motivated to avoid that harm (e.g., Anderson and Bushman, 2002; Bushman and Huesmann, 2010). Such a definition is wide enough to capture the full range of aggressive behaviors, and to make allowance for activities that can 'hurt' a target person but to which the target of the hurt willingly consents (such as undergoing surgery or engaging in sadomasochistic sex).

The second issue is that many laypersons and misinformed professionals use the term aggression interchangeably with related but conceptually distinct phenomena such as anger, hostility and competitiveness. There is no question that in the field of psychology, aggression refers only to a behavior, and not to a mindset or an emotional state. Feelings such as anger, attitudes such as wishing the worst for another, and motivations such as the desire to win or control one's environment may contribute to a person behaving aggressively but are not aggression per se. To study aggression effectively, such factors need to be clearly differentiated from aggression and from each other.

A third definitional issue involves the common practice of using the term 'violence' interchangeably with the term 'aggression.' Treating these as synonymous creates miscommunications and confusion among researchers, public policy-makers, and the general public. Among most social psychologists, violence is a subtype of aggression. More precisely, 'violence' is aggression that is intended to cause harm extreme enough to require medical attention or to cause death. Many social psychologists extend this definition to include causing severe emotional harm. Thus, all violent behavior is aggression, but most aggression is not violence. Note that this definition of violence is not synonymous with 'violent crime,' which is a legal term, not a scientific one.

Types and Characteristics of Aggression

When considering the many ways in which one human can harm another, it is useful to distinguish between different forms of aggression, and between the different functions that aggression can perform. Different forms of aggression include physically harming another (i.e., *physical aggression* such as hitting, biting, kicking, clubbing, stabbing, shooting), hurting another with spoken words (i.e., *verbal aggression* such as yelling, screaming, swearing, name calling), or hurting another's reputation or friendships through what is said to others verbally or digitally (i.e., *relational aggression*). Aggression may also be *direct* (with the victim physically present) or *indirect* (enacted in the absence of the victim; for example, smashing someone's property or spreading rumors about them).

Aggression also differs by function. It may involve a relatively pure intent to punish/hurt the target person, as in

reacting aggressively to provocation (i.e., *reactive, affective, hostile, hot, impulsive*, or *retaliatory* aggression) or it may involve a considered and deliberate plan to harm another to gain a desired outcome (i.e., *instrumental, proactive, planned*, or *cold* aggression). Aggression may be an *automatic* response driven by hard-wired self-protection mechanisms (e.g., fight or flight) or involve a script for aggressive behavior that is so commonly enacted that the response is no longer thought-through. Of course such distinctions can be problematic. What about a person whose rage drives them to carefully plan the death of another? Such instances do not fit any of these traditional categorical or dichotomous distinctions. A viable alternative approach to understanding the function of aggression is to locate aggressive acts on three dimensions – the degree to which the goal is to harm the victim versus benefit the perpetrator; the level of hostile or agitated emotion that is present; and the degree to which the aggressive act was thought-through (Anderson and Huesmann, 2003).

Social Psychological Theories of Aggression

Theories Outside Social Psychology

This article is focused on the social psychology of aggression, but must be considered as complementing research from other spheres of psychology. Most notably, biological psychology provides many relevant findings, including links to genetic predispositions, hormones, malformation, or damage of brain structures and levels of cortical and nervous system arousal. Psychodynamic approaches and animal psychology have emphasized aggressive drives, and evolutionary- and animal psychology have focused on aggression in terms of factors related to reproductive success and survival (e.g., dominance and resource-holding potential). Social psychological approaches have tended to include such biological, genetic and personality factors as 'person' factors in their models, but typically have not explored detailed interrelationships among these and related social factors.

Early Social Psychological Theories

For more than 70 years, social psychology has provided a variety of frameworks from which hypotheses about the causes and consequences of aggression could be derived and tested. These theories, although distinct, have also tended to overlap as new knowledge has extended an existing framework of aggressive behavior. The earliest influential theory from social psychology was the frustration-aggression hypothesis.

The Frustration-Aggression Hypothesis

During 1939, partially in response to World War II and partially in response to the spreading influence of psychodynamic theories in the US, Dollard et al. (1939) proposed the first systematic theory of aggression. Using assumptions from psychoanalytic theory, they focused on the frustration caused when a goal is blocked, and suggested that "the occurrence of aggressive behavior always presupposes the existence of frustration," and that "the existence of frustration always leads to some form of aggression" (p. 1). Although this theory enjoyed some empirical support, it quickly became obvious that frustration does not always lead to aggression, and that not every act of aggression can be traced back to frustration. Frustration-aggression theory was revised to incorporate the possibility that frustrations can elicit responses other than aggression (e.g., to escape or to find another way to achieve a goal), and that the inclination which will be acted upon is the one that best reduces frustration. In this revised formulation, people learn through experience to respond to frustrations with aggressive or nonaggressive responses.

Learning Theories

The earliest theory of learning in modern psychology explains behavior in terms of *classical conditioning* – learning to associate one thing with another. Pioneered by Pavlov, this approach suggests that once people mentally pair things together, they become 'conditioned' to expect those things to always occur together. This theory was later supplemented with theories of *operant conditioning* developed by Thorndike and Skinner, which suggest that people are more likely to repeat a behavior that has been rewarded and less likely to repeat a behavior that has been punished. In aggression research it has been shown that children can be taught to behave aggressively through rewarding aggressive behavior (*positive reinforcement*) or removing a painful consequence after aggression (*negative reinforcement*). In addition, children learn to discriminate between situations where aggression has a desirable consequence and when it does not, and to generalize this knowledge to new situations. Although such research demonstrates that aggression can be learned through conditioning (e.g., Eron et al., 1971), it was clear by the 1960s that such processes could not explain the acquisition of all learned aggression.

Bandura proposed that social behaviors, including aggression, could be learned through observing and imitating others (i.e., via *observational learning*). In his classic experiments, children observed a film of an actor hitting a 'Bobo Doll' in several novel ways. The children later imitated the behavior in the absence of any classical or operant conditioning. Bandura also developed the concept of *vicarious learning* of aggression, and showed that children were especially likely to imitate models that had been rewarded for behaving aggressively. In *social learning theory* (later called *social cognitive theory*), Bandura hypothesized that the way people mentally construct their experiences is crucial. People may see one person hit another, but will also decide how competent they feel to do the same, and will make assumptions about what constitutes a normal way to respond when someone provokes you. In this way, making inferences about observed aggression not only increases the likelihood of imitating it, but also expands the range of situations to which that response might be generalized (see Bandura, 1986). There is considerable research support for social cognitive explanations of aggression. People sometimes imitate aggressive models, especially if the aggressive behavior is rewarded or carried out by a person who is heroic, admired, of high status, attractive, or similar.

Arousal: Cognitive Labeling and Excitation Transfer

The emergence of cognitive psychology inspired a plethora of new approaches to aggression by social psychologists. Early in this period, researchers explored the way people make meaning of physiological arousal, a known precursor to aggression.

Researchers such as Schacter found that when people are aroused, they look for cues in the environment to help them attribute the cause of their arousal. For example, Schacter and colleagues found that if aroused people were exposed to another person who was angry, they tended to *cognitively label* their arousal as being angry themselves. Zillmann (1979) extended this concept with *excitation-transfer theory* (ETT). Physiological arousal, however produced, dissipates slowly. ETT posits that if two arousing events are separated by a short amount of time, arousal from the first event will add to arousal from the second. However, the cognitive label given to the second event will be misattributed as being relevant to all of the arousal experienced, thus producing an inappropriately strong response (e.g., becoming angry to a level far greater than might be expected for a minor provocation). Because the cognitive label (or attribution) is crucial in determining behavior, strong anger related to excitation transfer may persist long after the arousal itself has dissipated.

Mainstream Cognitive Theories

Information Processing and Script Theories

The confluence of computer availability and the growing dominance of cognitive approaches to psychology in the 1980s heralded a major change of direction in social psychological aggression research. For the first time, researchers started to conceptualize the acquisition of social behavior in terms of computerlike processes – inputs, outputs, and the processing of information. Two key theories of aggression emerged – the Social Information Processing (SIP) theory of Dodge (1980) and Script theory from Huesmann (1982). SIP theory emphasized the way people perceive the behavior of others and make attributions about their motives. A key construct in SIP theory is the *hostile attributional bias* – a tendency to interpret ambiguous events (such as being bumped in a corridor) as being motivated by hostile intent. This bias has been extensively studied and has been found to reliably predict aggressive behavior.

Script theory emphasizes the acquisition of scripts for behavior (much like an actor's script) through either direct experience or observational learning. Once encoded in semantic memory, *scripts* define particular situations and provide a guide for how to behave in them. In script theory, a person faced with a particular situation first considers a script relevant to that situation, assumes a role in the script, assesses the appropriateness or likely outcome of enacting the script, and if judged appropriate, then behaves according to the script. If a person habitually responds to conflict by using scripts that include behaving aggressively, these scripts may become more easily brought to mind (i.e., chronically accessible), become automatic, and generalize to other situations, increasing the likelihood of aggression in a growing number of spheres of life.

Cognitive Neoassociation Theory

Cognitive Neoassociation Theory (CNA) reformulated the frustration-aggression hypothesis within the framework of emerging knowledge about neural connectivity. Assuming that concepts, emotions, memories, and action tendencies are interconnected within the brain's associative neural network, Berkowitz (1989) posited that aversive events such as frustrations, provocations, or unpleasant physical environments produce negative affect, which is neurally linked to various thoughts, feelings, and behavioral tendencies that are themselves linked to both fight and flight tendencies. Depending on the characteristics of the person and the situation, one response set will eventually dominate, with dominant 'fight' responses linked with anger and being more likely to elicit aggression. Importantly, higher-order processes such as making attributions about another's motives or thinking through the consequences of an aggressive response may cause a person to moderate an aggressive impulse in this model.

Current Theories

The General Aggression Model

The General Aggression Model (GAM; Anderson and Bushman, 2002) is the most recent and broadest theory of aggression processes to date. It is a biosocial-cognitive model designed to account for both short- and long-term (developmental) effects of an extensive range of variables on aggression. GAM can explain the widest range of aggressive behaviors, including those not based around aversive events or negative affect. In addition, it is arguably the model that has the most empirical support. GAM unifies previous major models of aggression from the field of social psychology into a single framework, but also incorporates knowledge from other disciplines in psychology.

The model itself is deceptively parsimonious. Every instance of aggression involves a person, with all their characteristics (e.g., biology, genes, personality, attitudes, beliefs, behavioral scripts), responding to an environmental trigger such as a provocation, an aversive event, or an aggression-related cue (lower portion of **Figure 1**). These *person* and *situation* variables influence the person's *present internal state* – cognitions, affects, and physiological arousal. Depending on the nature of activated knowledge structures (which include affect), and on how

Figure 1 General Aggression Model. From Anderson, C.A., Anderson, K.B., 2008. Men who target women: specificity of target, generality of aggressive behavior. Aggressive Behavior 34, 605–622. Reprinted by permission.

aroused the person is, the person's immediate response may be an impulse to aggress. The person may act on this impulse, but if they have the time and cognitive resources to do so, and if the immediate response is undesirable, a period of appraisal and reappraisal will follow. Consequences are then thought-through, alternate responses considered, and a considered response made. The resulting behavioral action may or may not be aggressive, but in any case all actions feed back into the immediate situation and also influence the person's psychological make-up (i.e., their personality).

Underlying the GAM are detailed assumptions that take into account a myriad of within-person factors, a range of possible triggers for aggression, known internal psychological processes, and the means by which behavior is reinforced and learned. In terms of the latter, knowledge structures such as schemas (a grouping of knowledge, feelings, memories, perceptions and notions about typical behavior that is centered around a particular theme) and scripts (knowledge about how people typically behave in a given situation such as during conflict) are person factors that can not only impel a person to be aggressive in the moment, but also change to reflect our experiences (upper portion of **Figure 1**). Thus, experience leads to changes in the type, content, and accessibility of knowledge structures, which are seen as the basis of personality.

Together, these features of GAM can be used to explain short- and long-term aggression across a range of forms and functions, including the three key dimensions already noted: degree of hostile/agitated affect; degree of automaticity versus conscious thought; and degree to which the goal is to harm the victim versus benefit the perpetrator. Phenomena as different as sexual and nonsexual aggression against women (e.g., Anderson and Anderson, 2008), personality effects on violent crime (Hosie et al., 2014), and dozens more are well explained by GAM.

Aggression Research Methodologies in Social Psychology

As a social behavior, aggression has been primarily studied using methodologies from social psychology. Each of these methodologies has specific strengths and weaknesses, but, importantly, the shortcomings of each methodology can be overcome with the strengths of another. This allows aggression researchers to be strongly confident of an effect where findings converge across methodologies (Warburton, 2013).

Laboratory Assessments of Aggression

Laboratory experiments provide the strongest evidence that a particular factor may play a causal role in aggression. This is because that factor can be manipulated whilst all other factors are (in theory) held constant (e.g., all participants may have an identical experience in the laboratory except for watching a violent or a nonviolent movie clip). Aggression experiments typically measure short-term increases in mild forms of aggression or in known precursors such as aggressive thoughts and feelings. For example, researchers might measure whether aggression-related thoughts are more activated in one group of participants compared with another by testing reaction times to identify aggression-related (hit, blood) versus neutral (sew, rose) words. Aggressive feelings are typically measured by having participants rate the degree to which they feel emotions such as anger, antagonism, and unfriendliness.

Measuring aggressive behavior itself has a long history involving ethical, reliability, and validity concerns. For ethical reasons, serious harm cannot be used as an aggression measure in laboratory experiments. However, numerous valid and reliable aggression measures have been developed, usually involving a contrived laboratory situation that allows participants to behave in a way that they *believe* will harm another, but in which no person is actually hurt. Early measures included counting the number of aggressive acts a child would make toward a target, and the willingness of an adult to deliver a (fake) electric shock to another person purportedly being tested for their ability to memorize stimuli under conditions where they would be 'punished' for mistakes. More recent methods include measuring the duration and/or loudness of aversive 'noise blasts' delivered to an opponent in a competitive reaction time (CRT) game, the amount of hot chili sauce assigned for eating by a stranger known to dislike hot foods, and the number of difficult puzzles that require solving by another person in order to win a reward. Although such measures have been criticized for being unlike 'real-world' situations and subject to biases such as the desire to please (or displease) the experimenter, well-designed modern experiments overcome such problems using careful cover stories and scripts, and have been shown to predict real-world aggression.

Nonexperimental Research about Aggression

Nonexperimental research has the distinct strength that it can examine a wide range of 'real-world' aggressive phenomena and can be used to examine longer-term effects such as the development of a more aggressive personality. *Longitudinal studies* (in which key variables are measured at multiple points in time) are particularly valuable, because they can measure the development and change of aggression over time within individuals, and examine long-term effects of wideranging factors such as home environment, personality, and media violence exposure. In addition, the logical impossibility of a later-introduced factor causing an earlier-mentioned behavior, along with use of recent advances in statistical techniques, allow some causal inferences to be drawn.

Cross-sectional studies (in which all variables are measured once) are also valuable, but require cautious interpretation. Causal inferences are risky, because of the possibility that not all relevant factors were measured and taken into account. Nevertheless, such research has contributed substantially to theory testing and development by providing the opportunity to test causal theory-derived hypotheses and alternative explanations to the causal theory.

Observations of Aggression in Social Psychology

Some of the earliest and most powerful social psychological research of aggression was conducted through observational research, some in the laboratory (e.g., Bandura's Bobo Doll experiments) and some in the field (e.g., studies of aggression on playgrounds). Such studies have the distinct advantage of

observing and recording actual rather than self-reported aggressive behavior, often in the participants' natural environment. Importantly, issues that sometimes arise from self-report questionnaires (e.g., biased responding, lack of self-awareness or capacity to report thoughts and feelings) are not relevant, and populations unsuitable for other forms of research (such as young children) can be examined. However, aggressive behaviors often have a low incidence in observed environments, and ratings of aggression can be somewhat subjective. Researchers overcome the latter issue by creating clear and comprehensive guidelines, detailing behaviors that should be coded (e.g., pushing, shoving, hitting, name calling), and thoroughly training the raters. Also, self-reports may be supplemented by reports of relevant others (e.g., parents, teachers and peers). Indeed, converging data from multiple sources often provides the strongest evidence (Anderson et al., 2007; Warburton, 2014).

Brain Scanning Techniques to Study Aggression

Social psychologists are now using brain-scanning techniques to study aggression, most notably in the field of media violence. Such techniques have the advantages that they can be used on many types of participants, participants cannot 'fake' their responses, and participants do not have to be self-aware to provide valid responses. Brain scans are particularly valuable for assessing factors difficult to measure using other methods such as desensitization to violence, fear responses, and emotional arousal. Functional magnetic resonance imaging (fMRI) studies identify brain activity by measuring changes to blood flow, but are accurate only to a few seconds across time. Brainwave activity measured by electroencephalography (EEG) and magnetoencephalography (MEG) are extremely accurate in terms of the timing of changes to brainwaves, but cannot give accurate locations within the brain. Thus, using both techniques to study the same hypotheses leads to better understanding. Brain-scanning studies have some drawbacks – they generally use small samples because of the cost involved, they need to average images using sophisticated software and sometimes their data are hard to meaningfully interpret.

In typical aggression studies, participants are scanned whilst experiencing one or more stimuli (such as playing a violent or nonviolent video game) or doing various tasks, such as rating different types of pictures or making decisions. Thus, researchers can compare activation patterns to determine whether changes (such as desensitization) occur over time, one type of stimulus has different effects than another, or different groups (e.g., high vs low media violence consumers) typically respond differently.

Research Findings: Determinants of Aggression

Development and Stability Over Time

Scholars studying social development have shown that the frequency of physical aggression typically peaks in the toddler years and then decreases across the life span. Importantly, the degree to which one person is aggressive relative to others of the same age is fairly stable across the life span. Aggressive children tend to become adolescents and adults who are more aggressive than their peers (Bushman and Huesmann, 2010).

Person Factors

Numerous factors in a person's make-up have been shown to increase the likelihood of aggressive behavior. Not all are studied directly in social psychology, but all are taken into account in current social psychological models of aggression.

Gender Differences in Aggression

Overall, males are generally more aggressive than females, and this applies from early in childhood through the life span. This is especially true for physical aggression and violent behavior, although women are as physically aggressive as men when strongly provoked. Men are more likely than women to use direct forms of aggression, but the reverse is true for women, who are more likely to use forms of indirect aggression, including relational aggression.

Within intimate relationships, however, women are somewhat more likely to use physical aggression than men, though for different purposes and with different results. For example, men are much more likely to strike with a fist (women with an open slap), which is one reason why intimate partner violence yields many more women requiring medical attention than men.

Trait Anger

Trait anger reliably predicts an aggressive predisposition. It is characterized by extreme sensitivity to provocation and a considerably increased inclination to respond with aggression once provoked.

Callous Unemotional Personality Traits

There are three personality styles under this umbrella – psychopathy, Machiavellianism, and narcissism. All three are linked with high levels of aggression, lack of empathy, and curtailed emotional responding. Individuals of all three types routinely use aggression instrumentally to obtain desired goals, but narcissists and psychopaths are also prone to reactive aggression. Narcissists often respond aggressively when they feel threatened (particularly by insults, humiliations, or other threats to their inflated ego), or when they fear that their flaws may be exposed. Psychopaths, particularly those with secondary psychopathy characteristics, are often impulsive, fearless, and unconcerned about negative consequences to themselves or victims – a potent mix for a person already predisposed to aggression. Machiavellians most typically use instrumental aggression to achieve their goals and feel little or any remorse for harmful consequences to others. They do, however, consider potential consequences to themselves, and are thus more likely to aggress indirectly so that there is little likelihood of being held responsible for their actions.

Impulsivity, Executive Control, and Self-Control

Impulsivity is a temperament variable often noticeable from early infancy, and is a reliable predictor of aggression, presumably because impulsive people have difficulty curbing aggressive impulses. In contrast, people are less aggressive if they have greater control over their emotions, greater

self-control, and a stronger capacity to inhibit their impulses (Moffitt et al., 2011).

Intelligence

There is not a great deal of research on IQ and aggression, but some studies have found links between low IQ and higher levels of aggression in children, particularly in children with poor verbal intelligence and/or with low self-control.

Personality Traits – The 'Big Five'

Research on the 'Big Five' personality traits and aggression has generally found that people low in agreeableness and high in neuroticism are more aggressive and violent. Furthermore, both of these dimensions are associated with aggressive emotions, and low agreeableness is also associated with greater aggressive thinking (Barlett and Anderson, 2012).

Hormones

The hormone most consistently linked with aggression is testosterone. Males have around 10 times as much testosterone as females, and levels are much high in older teenagers and young adults than in older men. Interestingly, when people dominate others, their testosterone levels typically increase, along with their levels of aggression. There also is evidence that testosterone's effect on aggression is a by-product of its effect on dominance. There also may be links between low levels of estrogen and progesterone and aggression, although results are mixed. Finally, emerging evidence suggests that low levels of oxytocin may be linked with increased aggression.

Genetic Predispositions

Although aggressive behavior has a considerable learned component, studies show that inherited characteristics account for perhaps a quarter to a third of an aggressive predisposition (Tuvblad et al., 2009). More than a dozen genetic markers have been linked with aggressive and antisocial behavior, although links are rarely direct. Typically, genetic predispositions more directly relate to temperament variables such as impulsivity, which are themselves linked with greater aggression. The two most widely studied genetic markers of aggression are a polymorphism in the promoter of the monoamine oxidase A gene (MAOA) and a variation in the 5-HT serotonin transporter gene. Crucially, in line with the emerging field of epigenetics, the MAOA gene polymorphism seems to interact with a child's early environment, so that aggression and antisocial behavior are most likely in those who have this genetic trait *and* also experience childhood maltreatment (Kim-Cohen et al., 2006).

Factors from the Environment and Cues for Aggression

Provocation

Perhaps the single greatest trigger for aggression is provocation by another person (Bettencourt et al., 2006). However, provocation does not need to be direct. People can be provoked to aggression by social exclusion, having rumors spread about them and a range of other 'indirect' provocations.

Weapons

Weapons are one stimulus that almost all people conceptually link with aggressive behavior. Research consistently shows a 'weapons effect' whereby people who view a real or virtual weapon tend to have aggression-related cognitions primed in semantic memory, and become more likely to behave aggressively. Interestingly, this effect varies by type of weapon and hunting experience (see **Figure 2**).

Violent Environment

According to social cognitive models, people who are exposed to a lot of violence, virtual or real, will have an associative neural network with a lot of aggression-related knowledge structures, including aggressive behavioral scripts. This is borne out by research demonstrating that people from violent environments, whether homes, neighborhoods, or war-torn countries, have a greater predisposition to be aggressive (e.g., Aguilar et al., 2000).

Violent Media

The same principle applies to exposure to violent media. It is one of the most studied phenomena by social psychologists, and several hundred studies converge across all major research methodologies in finding that violent media exposure increases the likelihood of aggressive behavior and causes desensitization to violence in both the short- and long-term (Warburton, 2014). In addition, greater exposure to media violence has been linked to hostile biases in thinking, increases in aggressive thoughts and feelings, and decreases in empathy and prosocial behavior (see Anderson et al., 2003; Krahe et al., 2012, for reviews).

Environmental Stressors

A variety of environmental stressors can increase the tendency to aggress. The most notable are physical pain, bad-smelling odors, loud or aversive noises, and hot temperatures. Importantly, it seems that aggression is most likely when the individual has no control over those environmental stressors.

Anonymity

Anonymity in some circumstances increases the likelihood of aggressive behavior. It is much easier to hurt another

Figure 2 Aggressive behavior (number of high-energy noise bursts directed at the opponent) as a function of hunter status and weapon prime. From Bartholow, B.D., Anderson, C.A., Carnagey, N.L., Benjamin, A.J., 2005. Interactive effects of life experience and situational cues on aggression: the weapons priming effect in hunters and nonhunters. Journal of Experimental Social Psychology 41, 48–60. Reprinted by permission.

if an individual believes there will be no consequences, and anonymity allows a person to experience 'deindividuation' – a lessening of the restraints on antisocial behavior normally accorded to people perceived as being 'individuals.'

Social Rejection

Humans have a fundamental need to feel socially included and to have supportive and enduring relationships. When this need is thwarted through social exclusion or rejection, people sometimes behave more prosocially to facilitate reinclusion. However the dominant response to such rejection is to aggress, especially when the person can do so without significant social reprisals (e.g., Warburton et al., 2006).

Substances

Alcohol intoxication consistently causes both men and women to behave more aggressively inside and outside the laboratory, and is linked with a substantial proportion of murders, assaults, rapes, and incidents of intimate partner violence. Importantly, this increase is due to the aggressor experiencing a diminished ability to inhibit their aggressive impulses. Thus people who are predisposed to behave aggressively are most affected (Giancola, 2000). Aggression has also been linked with other substances that cause disinhibition and/or an increase in physiological arousal, such as stimulants, amphetamines, and methamphetamines.

Research Findings: Factors that Mediate Aggression

The previous section examined factors within the person and in the environment that can trigger or increase the likelihood of aggression. This section deals with the three key types of internal processes noted in GAM that can increase or decrease the likelihood of aggression.

Emotion/Affect

Early models of aggression placed considerable emphasis on the role of negative emotions in causing aggressive behavior, and research has linked several emotions to an increased likelihood of aggression, most notably anger, shame, jealousy, and frustration. Of these, anger is the most researched. Although anger can precede aggression, the pathway is far from a simple cause and effect. Anger increases aggression primarily through reducing inhibitions, narrowing attentional focus to cues for aggression, and alerting people to cues for potential threats (see Anderson and Bushman, 2002). Shame has also been linked to increases in aggression, primarily when the shamed person feels their personal flaws have been exposed. Jealousy has also been linked with aggression and in particular with intimate partner violence.

Recent research suggests that the anticipation of how one will feel in the future can be as important as how one currently feels in determining whether a person will be aggressive.

It should be noted that some emotions can be a protective factor for aggression. For example, empathy (taking another person's perspective and having concern for them) is consistently related to lower aggression.

Cognition

Recent models of aggression have focused increasingly on the cognitions that may underlie aggression. These include attitudes, beliefs, expectations, perceptions, ideas, and concepts as well as aggregated cognitions such as schemas and scripts. It is clear that a variety of external triggers can increase the accessibility of aggressive cognitions in semantic memory. These cognitions may be activated but below the threshold of awareness, or activated to the point of conscious awareness. In either case they can elicit an aggressive behavioral tendency through the priming of aggression-related action-tendencies, the activation of aggressive scripts for behavior, or through the influence of hostile biases on the interpretation of cues from the environment.

Arousal

Physiological arousal and emotional arousal are both linked with increased aggression, and this is true regardless of what caused the arousal in the first instance. This may be due to one or more of several factors. First, arousal increases the likelihood that a person will act on an aggressive action tendency or impulse rather than think through the consequences of an aggressive action. Second, excessive levels of arousal feel unpleasant, and can elicit aggression in the same way as other unpleasant experiences. Third, arousal may be part of a fight or flight response system that bypasses rational thought and impels aggressive action. Fourth, arousal may be cognitively labeled as resulting from anger, thus causing the person to feel and act angry. Excitation transfer may compound this effect, leading to a disproportionately aggressive response. Finally, low levels of arousal may facilitate aggression if people lack the energy and motivation to inhibit aggressive impulses.

Societal Aggression and Violence – a 'Risk Factor Approach'

It is one thing to know the types of factors that increase the likelihood of aggression, but quite another to understand aggression and violence in wider society. No single factor described in this article is either sufficient or necessary to elicit violent or other extreme forms of aggression. These only occur when there is a confluence of 'risk factors' for aggression (such as those detailed in this article) and insufficient 'protective factors' to inhibit aggression. The greater the number of risk factors and the stronger their influence, the more likely it is an individual will behave aggressively, especially when protective factors are few or of little impact (Anderson et al., 2007). The problem for researchers is that the greater the number of risk factors they need to consider when studying aggression and violence, the more difficult it is to determine how the factors interact with each other, and to ascertain the relative impact of each on an act of aggression or violence. However, this is the task that faces social psychologists as they try to make sense of mass killings, school shootings, and societal violence. Importantly, the more that is known about risk factors and protective factors, the greater the ability of psychologists to understand

and prevent societal violence, and indeed aggression in everyday life.

Conclusions

Human aggression has been researched by social psychologists and others for many decades. The result is a large body of knowledge about the factors within people and from the environment that increase the likelihood of aggression, along with a more detailed understanding of the processes that occur in the mind and brain during an instance of aggression. Well-validated models such as GAM have been built around these findings. Less is known about the ways in which risk factors for aggression and violence interact with each other and with protective factors. Still, much is known about how to decrease the likelihood of societal violence. Yet, this knowledge is, in our view, not sufficiently used in society at large.

One ongoing world crisis illustrates this problem. Global climate change as a result of human activity is now a widely (though not universally) accepted fact. In combination with work from a variety of biological, sociological, historical, and anthropological, findings, GAM suggests that there are at least three ways that such rapid global warming will increase violence worldwide. The most direct is the simple heat effect mentioned earlier. A second way is that increased poverty, malnutrition, and family disruption will increase the proportion of children who develop into aggression-prone adolescents and adults. The third way involves ecomigration, the movement of populations from ecological disasters to other regions, and the intergroup conflicts that will result (Anderson and DeLisi, 2011). We hope that the knowledge gained by decades of aggression research in social psychology will be put to better use in the future.

Abstract

The article chronicles the history of AGIL, the best-known conceptual scheme associated with the work of Talcott Parsons. It starts reviewing the theoretical elements of Parsons' early work that have played a role in his design of the AGIL scheme in the early 1950s. It describes the various development of the AGIL scheme in his subsequent work. It concludes with an assessment of its contemporary relevance.

Introduction to Parsons and AGIL

Both in textbooks and in disciplinary lore, even the most cursory reviews of the work of Talcott Parsons never fail to mention AGIL, an acronym composed of the initials of what he claimed where the four analytic dimensions of any action system: adaptation, goal attainment, integration, and latent pattern maintenance. It is difficult to underestimate the importance Parsons attributed to his invention. For him, AGIL was a generalized template for sociological models. For more than 25 years, he tried, whenever a problem was posed, to show that it could be addressed through the construction of a model satisfying the AGIL requirements (Fararo, 2001). He insisted AGIL was a consistent conceptual scheme, able to highlight the multidimensional nature of social life, clarify disciplinary boundaries, and trigger comparative work across all the social and life sciences. He declared that the development of AGIL had made possible a theory of long-term social change, energized by the pressure of a plurality of independent problems.

Parsons felt AGIL was the very embodiment of his lifelong search for multidimensional analysis (Alexander, 1984). He claimed AGIL was able to overcome any opposition between material and ideal factors and to dispense with the limitations of any base–superstructure model. Unsurprisingly, Parsons applied the AGIL scheme – usually in the graphic form of four-squared boxes, each of them further subdivided by four – to an astonishing range of analytical levels and empirical issues (Parsons, 2007). In his writings, the reader can find AGIL of families, university systems, world societies, civilizations, churches, and small groups. He even applied AGIL to the mysteries of the human condition itself (Parsons, 1978).

Equally unsurprising, many of his critics have used AGIL as their primary foil. Some have seen in it the proofs of Parsons' endemic tetra mania; some others have argued that its formal elegance has been just the cover for lousy arguments held together by elimination, implication, and superficial analogies; still others have claimed AGIL needlessly restricted the possibilities of theoretical thinking in the social sciences (Mulkay, 1971; Luhmann, 1988; Stinchcombe, 1975). Whatever the judgment on AGIL's intrinsic worth, it is difficult to deny that it is one of the most wide-reaching and technically complex conceptual schemes ever developed in the social sciences.

Before AGIL: Action, Situation, and Normative Patterns

Given the core location of AGIL in Parsons' work, it may be a surprise that AGIL is actually a late product of his career. Many of the major works traditionally associated with Parsons (roughly from *The Structure of Social Action* to *The Social System*) have actually been published before the appearance of the scheme. AGIL is consequently a mature development, which both strengthen and innovate Parsons' earlier approach. If Parsons felt AGIL was of particular importance, it is precisely because he identified in it a solution to a cluster of theoretical problems that had shaped his previous work.

Parsons' sociological theory centers on the question of how a shared system of social expectations may regulate and sustain the interaction among a plurality of independent actors. His starting point is the critique of previous social theories for their failure to develop a sociological view of the problem, falling back to extra-sociological factors such as biological heredity or environmental constraints. In his view, on the contrary, actors have no predetermined – biologically or environmentally – mechanisms of coordination (Parsons, 1937). A satisfactory understanding of human action has to assume the *analytical* independence among the personality of the actor, the cultural values, and the requirements of social interaction. Parsons adopts a stance of *institutionalized individualism*, where the actors' agency is not a theoretical given, but rather the outcome of a to-be-investigated socialized growth process where social relationships and cultural templates play a crucial role (Bourricaud, 1977). If actors are independent, any interaction presents a certain degree of uncertainty and risk for all those involved (Parsons, 1951). How can a plurality of independent actors achieve – and take for granted in their everyday activities – an adequate level of coordination and reciprocal understanding? Parsons think there is only one way to contemporize individual agency and social order: the existence of a shared system of normative expectations (Parsons, 1968). This possibility is rooted in the fact that social action – albeit voluntary, goal oriented, and subject to multiple selective criteria – is not idiosyncratic. The meaning of each action – for the actor herself and for any other observer – is contingent upon the matching between the motivations of actors and the (shared) perceived meaning of their interactional objects (or partners). Parsons distinguishes three kinds of perceptive and evaluative choices: cognitive, cathectic

(i.e., emotionally charged), and evaluative (Parsons and Shils, 1951). Any action requires learning about the potential objects and their relationships, feeling them as desirable or undesirable, evaluating them one against the other drawing upon (normative) assessment of their importance. Such subjective judgments are not solipsistic: they have to be understood by interactional partners, who have no access to the internal states of the actor. They rely upon (respectively) cognitive, cathectic, and moral norms, functioning as shared expectations on how the interaction partners (and the personality of the actor) will receive the action itself (Parsons, 1968).

Parsons summarizes the choices faced by the actors through what he calls 'pattern variables,' a small set of five polarized alternatives that constitute the meaning of the situation from the point of view of the actor. Three of the pattern variables refer to individual motivations and values:

- *Affectivity versus affective neutrality*. This includes the choice between immediate gratification and postponement, as well as the choice between charging the object with an emotional meaning or assessing it for its consequences for other purposes.
- *Universalism versus particularism*. This refers to the choice between treating the object as the member of an abstract, generalized category, or in terms of the specificities of its relationship to the actor.
- *Self-orientation versus collectivity orientation*. This is the choice between approaching the object as an individual or as a member of a collectivity the actor is member of (**Figure 1**).

If actors have no predetermined wishes and wants, social objects have no predetermined meanings and usages. According to Parsons, two further pattern variables are consequently needed in order to reduce the ambiguities over the nature of the social objects:

- *Quality versus Performance* (often also labeled as *Ascription vs Achievement*). This is the choice between quality and usability, between seeing the object as valuable in itself or as instrumental for other purposes.
- *Specificity versus diffuseness*. This is a choice between allowing objects to expect a specific set of behaviors or to entrust them with an open-ended set of expected dealings (**Figure 2**).

Pattern variables are elements that structure, in different ways and from different angles, the orientation of personality systems, the value patterns of cultural systems, and the normative structures of social systems (Parsons, 1960b). The degree to which actors assume appropriate selections among the (above mentioned) choices is what guarantees a certain level of mutual predictability and reasonable chances of cooperation among the actors, without – at the same time – precluding the pursuit of independently elaborated goals. Parsons identified two social processes through which actors' orientations could be coordinated: socialization, through which cultural patterns become (or fail to do so) selectively incorporated in personality systems and institutionalization, through which the same cultural patterns are selectively embedded (or fail to do so) in the distribution of actual social rewards (Parsons and Shils, 1951).

The economists use perfect competition and market equilibrium as natural benchmarks against which to study all other market structures. Parsons decided to proceed along similar lines, starting with the case of the (ideal) social situation where socialization and institutionalization are consistent and perfectly tuned. In such an ideal case, that Parsons calls "complete institutional integration of individual motivation," the actors desire and pursue socially desirable goals having access to socially prescribed means. The structure of their interaction, moreover, is such that their actions bring positive assessments by the other interactional partners of their performance, thus ensuring satisfactory outcomes. Parsons stressed that the "complete institutional integration of individual motivation," as the subsequent AGIL equilibrium, was neither an empirical description nor a normative ideal. It was just an abstract point of reference, a comparative criterion for assessing the relative distance of the various empirical contexts. Through his emphasis on socialization and institutionalization, Parsons was able to define the social system as having an integrative function for the whole action system, as it was social interaction that tied together and made compatible social, cultural, and personality elements of any (analytically understood) social action (**Figure 3**).

Until the end of the 1940s, however, Parsons had not yet developed a theory of the social system. While he was able to discuss analytically the role it played in the regulation of individual actors, he had no systematic theory of its articulation. He was not able to describe the processes through which it could maintain a minimal strength and consistency of the normative structure of expectations. Above all, he was not able to anchor systematically the cluster of pattern variables with an independent vision of social structures (Parsons, 2010). In *The Social System*, his most well-known book (and in many previous empirical essays), Parsons distinguished only two functional problems. Any social system – from a couple to a world society – has to deal with (1) the allocation of resources among the various units and (2) the compatibility among its various institutions, through methods of social control and procedures for managing disputes and strains. The first has to do with scarcity: any social system may distribute less facilities and rewards than it would be (ideally) necessary to satisfy all individual motivations of participants (Parsons, 1951). The second has to do with diversity: actors have goals and expectations independent from the context; are loyal to different groups; and they are able to interpret social values in different ways. The integration of a social system requires consequently the existence of processes able to regulate their goals (and loyalties, and interpretations) in ways compatible with the maintenance of the social system as a solidary collectivity. Doing so, however, Parsons incurred in the same problems he had criticized in the early functionalists: the provision of an indefinite list of functions justified by their empirical significance rather than by their inclusion in a consistent analytical framework. This usage, Parsons stressed, had favored the proliferation of new functions on ad hoc basis, thus weakening the appeal of functional analysis (Sciortino, 2008).

The Early AGIL

The roots of AGIL lye in several collaborative projects Parsons was involved at the end of the 1940s and for all of the early

Figure 1 Parsons T., Bales R., Shils E., 1953. Working Papers in the Theory of Action. The Free Press, New York, p. 182.

1950s. Two key figures in the early development of AGIL were Robert Bales, the social psychologist who had pioneered the systematic observation of group processes, and Edward Shils, who was then working on the role of symbolism in the regulation of social interaction (Parsons and Shils, 1951; Parsons et al., 1953). Other colleagues – among them Gordon Allport, Clyde and Florence Kluckhohn, James Olds, and Samuel Stouffer – provided important contributions (Parsons, 1977).

The starting point for the design of AGIL was the IPA framework devised by Bales to account for his observations of interaction in small groups (Bales, 1950). He clustered the problems encountered by the groups into four functional categories, deemed independent from the contents of the various exchanges within the group. Any human group had to face the pressure deriving from (1) the adaptation to external conditions; (2) the instrumental controls over the goals of members necessary to the management of collective tasks; (3) the expression of the motivational energies of members; and (4) the maintenance of its coordination mechanisms (Parsons et al., 1953).

Bales' analysis was important to Parsons for several reasons. First, Bales' model did not postulate the primacy

Figure 2 Parsons T., Bales R., Shils E., 1953. Working Papers in the Theory of Action. The Free Press, New York, p. 203.

of certain problems over others, not even 'in the last instance.' Second, it showed how external pressures did not dictate the reaction of the groups, as they also had an internal dynamic that made possible a variety of outcomes. Third, it was compatible with what Parsons had tried to achieve with the pattern variables, as it linked analytically the motivation of members with the structural dynamics of the group.

Bales, Parsons, and Shils produced a collection of papers in 1953, *Working Papers in the Theory of Action* (Parsons et al., 1953). In his fifth, and conclusive, chapter the reader finds the very first version of the AGIL scheme. AGIL is presented as

Figure 3 Parsons T., Smelser N.J., 1956. Economy and Society, Routledge and Kegan Paul, London, p. 53.

a descriptive device, designed to summarize the temporal phases in the empirical development of a group. Ironically, the scheme that has often been criticized for its alleged conservative and static biases was born as a dynamic description of a social sequence. Graphically, the four 'problems' are placed along two axes: a vertical one linking the maintenance of psychological and cultural preconditions with the attainment of collective goals and a horizontal one linking external adaptation and integration.

After 1953, all subsequent works by Parsons have taken place within the idea that any action system (both individual action and social systems) has to deal with the following problems:

- *Adaptation* (A): the control and transformation of nonsocial resources;
- *Goal attainment* (G): the management of concerted action by the social units involved for collective purposes;
- *Integration* (I): the adjustment of relationship among the units of the system, the management of conflicts, and the settling of disputes;
- *Latent pattern maintenance* (L): the generation of long-term commitment to shared values and identities (Figures 4 and 5).

Parsons has also maintained across his subsequent work the special importance of the two axes, the vertical one linking L with G and the horizontal one linking A to I. Finally, Parsons maintained the assumption that no action system may satisfy all these 'problems' at once: therefore, there are always tensions and strains that require management and control. In other words, any social system has the same built-in tensions between actual and possible, between conditional and normative, that Parsons had previously placed at the center of his analysis of individual action (Fararo, 2001).

Since 1953, Parsons and his colleagues were increasingly outspoken in their claim that the AGIL scheme was potentially significant for any action system, regardless of size and complexity. What is more important, they claimed its discovery made possible to develop a structural analysis of social systems fully compatible with the subjective orientation of action. As some specific combinations of pattern variables could be shown to match a (independently generated) list of functional problems, this would take away from functional analysis the arbitrariness in the definitions of what counts as functionally important (Parsons, 1960a). They consequently linked some combinations of pattern variables to each of the identified 'problems' or dimensions of the social system:

- *Adaptation* is defined by specific and affectively neutral dispositions, and by a valuation of objects in terms of universalism and performance;
- *Goal attainment* (Bales' instrumental control) is defined by affectionate and specific dispositions, and by a valuation of objects in terms of performance and particularism;
- *Integration* is defined by affectionate and diffuse dispositions and by a valuation of objects in terms of quality and particularism;
- *Latent pattern maintenance* (at the time labeled, in a rather anodyne way, *Latent-Receptive Meaning Integration and Energy Regulation Tension Build-up and rain Off*) is defined by diffuse and affectively neutral motivations and by a valuation of objects in terms quality and universalism (Figures 6 and 7).

AGIL and the Cybernetic Hierarchy

During the 1950s, Parsons experimented with the AGIL scheme, applying it in many sociological analyses. He used AGIL to guide his, rather controversial, analysis of the modern American family (Parsons and Bales, 1955), as well as his, equally controversial, exploration of the relationships between economics and sociology, and between economy and society (Parsons, 1991). He also felt the need to revise his theory of social stratification along the line of the four-problem schema (Parsons, 1954). In his economic sociology, he identified the economy, in terms of the four-function model, as the adaptive subsystem of a society. He also defined the input–output categories traditionally treated in economic theory (as the factors of production

Figure 4 Parsons T., Smelser N.J., 1956. Economy and Society. Routledge and Kegan Paul, London, p. 68.

and the shares of income) as categories of *relation* between the adaptive subsystem and the other functional systems of the society (Parsons and Smelser, 1956). AGIL acquired then the nature of an exchange model, where its subsystems are analytically autonomous but organically interdependent as they provide each other with specialized resources. The exchange dimension of AGIL will become increasingly dominant in the subsequent elaborations by Parsons.

The first full-fledged technical discussion of the AGIL scheme appeared only in 1960. As the original one, it is centered on the relationships between the pattern variables and

Figure 5 Parsons T., 1960. Pattern variables revisited: a response to Robert Dubin. American Sociological Review 24, 467–483, p. 470.

the AGIL schema. Reacting to several critics, Parsons declares inadequate AGIL's early characterization as a phase model. He presents it as a dimensional template for the analyses of both action and social systems. He also finds a larger congruence between the pattern variables and AGIL: the 1953 combinations are casted as defining the subsystem of to the integrative system, and he proposes further combinations of them as appropriate for the psychological and cultural subsystems of action (Parsons, 1960a).

The original dynamic reading of AGIL does not, however, completely disappear. Parsons reformulates it through the claim that pressures and strains are managed, within any system, according to a hierarchy of control expressed in the form of a 'cybernetic hierarchy' (Parsons, 1960b). Such hierarchy – that later Parsons summarized as the inverse of AGIL, as LIGA – suggested that the more information-rich subsystem (L) would ordinarily enjoy a higher degree of autonomy from the net of structural interdependencies, thus being able to 'control' the changes taking place in them (Parsons and Platt, 1973). Parsons was keen to repeat that, in his view, cybernetic control did not imply domination in every respect nor the absence of feedback from lower, 'conditioning,' subsystems. Still, the lack of a convincing analytical justification for the notion has paved the way for the critique of the cybernetic hierarchy being a cover for his idealistic bias (Alexander, 1984).

Figure 6 Parsons T., Platt G., 1973. The American University. Harvard University Press, Cambridge, p. 426.

AGIL and the Study of Societies

Starting from the early 1960s, Parsons has developed AGIL in two directions: as a scheme for the analysis of the analytical structures of the social system, including modern societies, and as a template for the media of interchange, linking individual action and social structure. These are the best-known exemplars of Parsons' application of AGIL, although Parsons always stressed that 'societies' are a very specific and extreme form of the social system (Parsons, 1966).

When applied to contemporary societies – a term Parsons assumed, albeit with some perplexities, as closely approximated by the nation-state – the AGIL scheme identifies four distinct subsystems. Parsons sees modern society as structurally differentiated. Albeit all societies, as all social systems, are analytically differentiable in four subsystems, only in modern society such subsystems are 'structurally visible,' more closely – albeit never perfectly – associated with specialized structural units (Fox et al., 2005). The existence of clusters of functionally differentiated, largely autonomous, institutions and collectivities providing specialized contributions is what distinguishes modern society from previous forms of social organization (Parsons, 1966).

Parsons, drawing on his previous analysis, had already associated the modern economic institutions (broadly conceived) with the adaptive subsystem of a modern society, specialized in the development and allocation of fluid resources for a variety of goals (Parsons and Smelser, 1956). The next step was extending his line of reasoning to what he called 'the political system' – made of governmental bodies, as well as of nonpublic organizations – he associated with goal attainment (Parsons, 1969). He subsequently focused on the integrative subsystem. He coined the term 'societal community' for the subsystem specialized, following Durkheim, in the coordination between mechanic and organic forms of solidarity. He associated the integrative subsystem of modern society to the definition of membership, the management of the rights and duties attached to the system of social statuses, and the settling of disputes among competing loyalties (Parsons, 2007). In the same years, he explored what he called the fiduciary system, the latent pattern maintenance (L) subsystem of a society. The fiduciary system provides the cultural and motivational commitments necessary to a highly complex and highly pluralistic world. Parsons associated to such functions the institutions and collectivities crucial in the transmission and development of societal culture (Parsons, 1978). Each societal subsystem was further broken down by Parsons in its constituent parts (Parsons and Platt, 1973, p. 423–451). In all his AGIL reading of contemporary societies, Parsons described them as a complex web of conditional and normative elements, where a network of flexible interdependencies keeps together differentiated institutions and systems of complex solidarities.

From the mid-1960s, moreover, Parsons applied the AGIL schemes to problems of long-term social change. His vision of societal evolution can be described as a combination of Weberian and Durkheimian themes: through his writings, the master trends of social evolution are the breaking of the

Figure 7 Parsons T., Platt G., 1973. The American University. Harvard University Press, Cambridge, p. 436.

matrix of ascriptive relationships (a process that implies culturally the defamiliarization of the world) and the increasing adaptive capacity vis-à-vis the external environments. In his studies of social change, Parsons has applied AGIL both spatially and temporally (Parsons, 1971). Geographically, Parsons identified modernity with the birth of a system of modern societies, where different spaces and forms of social organizations play differentiated roles in the functioning of the international system. As for the second, Parsons accounted for modernity in terms of a (still uncompleted) sequence of changes in each of the subsystems. The transition to modern society initiates with the industrial revolution, centered on the economy (A). Such a differentiation process, however, requires broad changes in the institutions of collective decision-making process, what Parsons calls the democratic revolution (G). Such changes, however, trigger the possibility of a redefinition of societal membership in more inclusionary terms. With what Parsons calls the social revolution (I), a process broadly associated to the development of Western citizenship and the welfare state – modern society achieve a more inclusive societal community (Parsons, 2007; Sciortino, 2010). The everyday egalitarian interaction among members, however, requires an increased acceptance of diversity and pluralism. Such acceptance places pressures to the fiduciary system to detach the value system from any strictly defined tradition, thus further increasing what Parsons called 'value generalization.' Parsons thought that the main challenges to contemporary differentiated societies were rooted in the consequences of the inclusion processes (in the societal community) and the value generalization processes (in the fiduciary system). He claimed two further revolutions – the Educational and Expressive revolutions (L) – were underestimated but crucial events for contemporary societies (Turner, 1993, 2005).

AGIL and the Generalized Media of Interchange

Another direction in which Parsons developed the AGIL scheme was in linking structurally action and social systems through a set of mechanisms – that he labeled 'generalized media of interchange' – that would translate the outcome of social

interaction into the functioning of societal subsystems (and vice versa). He also entrusted such media with the task of providing the means for the interchange among the four societal subsystems. The blueprint for such set of mechanisms was money, the media that he had already analyzed in his economic sociology (Parsons and Smelser, 1956). He subsequently added power (G), influence (I), and value commitment (L) thus mirroring the four function systems with four function media (Parsons, 1969). Through such addition, he planned to show how the functional analysis of a social system was a necessary step for the development of a scientifically viable voluntarism. The base for the concept of media is a classification of the ways in which, given a double contingency interaction among independent actors, an actor may try to bring about a change in what the actions of other units would otherwise have been (Parsons, 1968). In other words, he focused on social coordination of voluntarist actors, within the same framework in which the analysis of socialization and institutionalization evolved. To classify the means available to the actor, Parsons selected two dimensions: the type of sanctions available to Ego in order to obtain Alter Ego compliance (positive *vs* negative sanctions) and the channel he can use to bring about such compliance (acting on the situation *vs* acting on Alter Ego intentions). He concluded that Ego could obtain Alter Ego's compliance in four ways: inducement, coercion, persuasion, and activation of value commitments.

Each of them has a symbolic element: even the most brutal coercion is meaningless without a previous communication of a contingent threat (Parsons, 1969). The sanction itself, moreover, may be symbolic, as in the case in which we transfer money or property titles. Parsons' emphasis on this symbolic element serves to bring attention to the fact that the interaction-level sanctions and rewards are interdependent with the four structural dimensions of societal systems. In Parsons' view, this symbolic element allows the use in the interaction of more resources than actually materially available in the environment at any given point. The capacity to emit a credible threat makes possible the control of many more actions and contexts than it would be possible in the case Ego had to back each threat with the actual use of physical force. In the same vein, the possibility to take for granted certain symbolically generalized commitment of Alter Ego, instead of making a detailed investigation any time, make possible a degree of trust far higher than otherwise. Parsons sees such expansion of interactional means as made possible by the structural anchoring of the interactional means in the institutionalized media related to the various subsystems (Parsons, 1969). In the modern economic order, the use of money in any interaction relies on the existence of an institutional order that simultaneously constrains and enables Ego in his choices. At the same time, the aggregate composition of Ego's spending decisions has effects on the state of the economic system in many ways, notably in determining processes of inflation and deflation. In a series of complex essay, Parsons argued that the same applies to all the other subsystems, though in different ways linked to the different natures of the media involved. The trick here is that what from the point of view of the actor is a means to further his own interests is a set of stability conditions for the institutional order (Parsons, 2007).

AGIL as a Tool for the Analysis of Action Systems, up to the Human Condition

Parsons had originally devised AGIL for the study of social actions. Starting from the end of the 1960s, after a long period marked by an overall concern with the analysis of social systems, Parsons returned to the original focus, now labeled general action system (Parsons and Platt, 1973; Parsons, 1977, 1978). He used the AGIL to summarize many of his lifelong claims on the multidimensionality of action and the positive interplay of individual agency and institutional regulation (Alexander, 1984). To reframe his earlier claims within the AGIL template, Parsons replaced the classification of culture, social system, and personality with a scheme of four primary subsystems. He had previously added, for the adaptive function, the behavioral organism, constituted of aspects of the individual organism that provide resources for physical behavior (Parsons, 1960b). He now aligned the personality with the goal attainment function because of the importance of psychological patterns of motivation to purposeful agency (Fox et al., 2005). He confirmed the role of the social system as integrative, as it provided the normative structures that regulated actors into common relationships and situations. He also confirmed culture as having primarily a pattern-maintenance function (Parsons, 1977). Each of them, in his most complex statement, was associated with a specialized media of interchange: intelligence (A), performance capacity (G), affect (I), and definition of the situation (L). Exactly, as for the social system, Parsons argued that each subsystem should be modeled according to the same AGIL template (Parsons and Platt, 1973, p. 436; Parsons, 2007).

In the last decade of his life, Parsons was also involved in an attempt to further generalize the scope of the AGIL scheme, in order to explore the connections between action and social systems – both made of meaningful actions – and the physical and biological bases of human societies. Focusing on what he defined as the 'human condition,' Parsons claimed that action systems could be seen as the integrative subsystem of a broader human condition involving also the physical environment (A), the organic, the human environment (G) and a telic, or transcendental environment (L). As in the previous efforts, he labored to provide such last scheme with its own media and interchange categories (Parsons, 1978; **Figures 8–11**).

Post-Parsonian Developments

Parsons' death in 1979 abruptly ended his efforts to explore and formalize the AGIL scheme further. In the subsequent decades, the evaluation of his overall legacy has become increasingly positive. Parsons has been increasingly recognized as a classic figure, able to open large issues, propose insightful and suggestive answers, and yet leaving significant problems unresolved and awaiting future contributions (Fox et al., 2005). The

Figure 8 Parsons T., 1978. Action Theory and the Human Condition. The Free Press, New York, p. 361.

Figure 9 Parsons T., 1978. Action Theory and the Human Condition. The Free Press, New York, p. 383.

AGIL scheme, however, has remained strictly associated with his work, failing to become a conceptual tool and theoretical technique used beyond the boundary of the circle of scholars interested in action theory. There have been some important attempts to increase its formalization of AGIL and to develop critically its theoretical potential (Brownstein, 1982; Loubser et al., 1976; Fararo, 2001). They have been unable to trigger a wider interest of the social science community. Even among the scholars who have done more to restore Parsons to a central position in contemporary social theory, there have been few attempts to use AGIL as little more than a source of broad inspiration (Alexander, 1984; Turner, 2000).

A search on Google Scholar with the key words *AGIL* and *Talcott Parsons* returns more than 1000 items for the period

Figure 10 Parsons T., 2007. American Society. A Theory of the Societal Community, Paradigm Publishers, Boulder, p. 88.

Figure 11 Parsons T., 2007. American Society. A Theory of the Societal Community, Paradigm Publishers, Boulder, p. 173.

2010–14. The scheme is, consequently, far from being forgotten. At the same time, most of the returned items deal with AGIL mostly in term of the history of sociological thought, or as a part of more broader discussions of Parsonian theory. Fresh applications of the AGIL scheme to new social science problems are a minority of the overall output. Is AGIL mainly a historical relic? As Zhu EnLai is said to have concluded about the French revolution, it may be too early to say. In fact, there are at least two ways in which AGIL maintains a contemporary significance in social theory.

First, AGIL is still a reference point for the few contemporary attempts to develop conceptual schemes for broad analyses of large-scale social systems. It is likely that AGIL has marked a point of no return, that has shaped, and shapes, the subsequent conditions for these intellectual projects. Its lasting achievement is the substitution of 'last instance' explanations – rooted in structure/superstructure assumptions – with analysis of interdependencies among analytically irreducible elements. After AGIL, comparisons among 'total' types of societies, previously common, have been increasingly rare, substituted with a nested level of analysis. The search of prime movers has also given way to inquiries into the modalities of coordination of the different.

Second, the AGIL scheme still plays a role in contemporary social theories in at least two further ways. First, there has been a looser understanding of the AGIL not as a technical scheme, but rather as a 'metaphor,' a source of inspiration for the possibilities of a nonrationalist, nonreductionist understanding of modern society. As an example, the neofunctionalist movement has adopted this nontechnical, metaphorical use of the AGIL scheme (Alexander, 1985, 1998). Second, some theorists have refused AGIL as a generalized template, but have adopted its relational logic in their own work (Donati, 2011; Habermas, 1981; Sciulli, 2010). Harrison White himself has also recently claimed the existence of interesting similarities between the AGIL scheme and contemporary work in network theory (White, 2008, p. 76). New encounters with AGIL may become more frequent in the future under the influences of two factors. The demographic change implies the emergence of a new generation of theorists who are emotionally detached from both the era of functionalism's centrality and from the 1960s' polemical reactions to it. For many of them, Parsons will be a classical theorist among many others, rather than a symbol of sanctity or pollution. Moreover, the contemporary theoretical agenda has again at its center some issues – such as the cultural dimension of social action, the need to integrate a variety of social coordination mechanisms, the key role played by societal pluralism, the new debates on modernity – that have inspired the construction of the AGIL scheme.

Abstract

Trends in mortality, disability, and chronic disease at older ages are described. Over the past several decades the years of life added as life expectancy increased resulted in more years of good health for the older population. In recent years, this trend appears to be reversing. Reasons for these observed trends in health indicators are described.

Over the last 50 years, life expectancy has steadily increased for both men and women in the United States. For much of that period, those years of added life were years free from disability. In the most recent period, however, that trend toward improvement may be stalling or perhaps even reversing. Understanding the changing pattern of the trend in health in later life has implications for individuals, families, and public spending. Changes on a number of dimensions of health in the elderly population (i.e., persons aged 65+) have been documented in recent US surveys. Similar to Manton (2001), I review the magnitude and substance of the changes in mortality, disease prevalence, and functioning and disability, and consider such of those factors that are shaping the current patterns and their implications for health and healthcare.

Introduction: Dimensions of Health

The definition of what is meant by 'health' is an important part of any discussion of health status. For many decades, mortality was assumed to be an adequate measure of the health of the elderly. Rapid mortality declines since the 1960s, especially for women, however, raised the question of whether these years of added life were years of good health. Answering this question has involved a considerable effort by researchers for the past several decades. One of the important early discussions of this topic outlined the link between different dimensions of health – mortality, disease prevalence, and disability. Crimmins (1996, 2004) discussed the interrelationship of the dimensions of health status and pointed out that due to differences in the processes driving each, we should not expect all measures to move in the same way over time. An examination of the health of the older population, and particularly the trends in health status, needs to look at all dimensions and take into account their differing influences.

Of most interest to many of those interested in the well-being and care of the elderly is the extent to which health problems limit activity or create dependency. Commonly referred to as 'disability' this is an important indicator of the health and well-being of the older population. Verbrugge and Jette (1994) coined the term disablement process to describe the interrelationship of disease, functioning, and disability. In this model, diseases are seen as creating impairments that lead to limitations in physical functioning. For instance, arthritis may create joint stiffness which results in difficulty bending or grasping an object. When limitations are severe they may interfere with the ability to carry out specific activities, resulting in a disability. Environmental factors are an additional component of the process. Individuals may be able to adapt to their environment, or their task, to accommodate their limitations. In those cases, they may delay the onset of a disability. In this framework, physical limitations are seen as coming before disabilities and more closely related to the underlying disease process.

There are three different models describing how disability may change in the US population. The failure of success model, expressed by Gruenberg (1977) argued that with improvements in the treatment of some chronically disabling diseases the US would enter a period of a 'pandemic' of chronic diseases and disability. That is, it was expected that persons with chronic diseases, and the profound disabilities they can generate, would survive many more years raising the prevalence of chronic disability and the average amount of lifetime that could be expected to be lived in an impaired state (Verbrugge, 1984).

A second perspective, due to Fries (1980), postulated that a 'compression of morbidity' would occur as life expectancy reached a maximum (estimated to be about 85 years). As this survival limit was approached the age range at which deaths occurred would become smaller, leading to a rectangularization of the survival curve. However, Fries suggested, at the same time the age of chronic disease onset could become compressed. As a result, most of life would be spent in an unimpaired state.

The third model suggested that the times of chronic disabilities and diseases onset could be in a dynamic equilibrium with survival (Manton, 1982). In this model, specific diseases may be affected by healthcare advances in differing ways. These differences would affect the relationship between mortality and disability so that both total life expectancy and disability-free life expectancy could be increased. This type of change would decrease the average amount of time spent in disabled states.

While these theories attempted to explain population differences in healthy life expectancy, new developments in the field of aging and health have focused on the role of genetics in affecting healthy survival. It has been commonly observed that longevity clusters within families, those with long-lived parents and siblings are more likely to have a long life themselves. More recent studies have shown that the children

of long-lived individuals, as well, have more favorable risk factor profiles and fewer age-related diseases (Newman et al., 2011). Despite the allure of finding a single 'longevity' gene, it is likely that several genes contribute to this effect, operating in many different ways. For instance, some genes may slow the aging process overall, while others may protect an individual from a particular disease.

Results from twin registry studies (Hjelmborg et al., 2006) and the Framingham Heart Study (Murabito and Lunetta, 2011) show that the genetic influences on longevity operate primarily above age 60. The heritability estimates for overall longevity range from 20 to 30%. The longevity phenotype, however, is very heterogeneous, including a wide range of physical and cognitive functioning levels. An examination of individual aging traits in the Framingham study shows varied heritabilities (Murabito et al., 2012). Physical frailty, for instance, showed a modest heritability, about 19%. But some less complex outcomes have higher heritability; measures of walking time and handgrip strength have substantial genetic contributions with heritabilities of nearly 40%.

Both individual and population measures of health provide important clues to the overall well-being of the older population and the outlook for future changes in health and functioning.

Mortality

Life expectancy itself is one important indicator of health status in a population and reductions in death rates are often used as an indication of improvements in health and well-being. Life expectancy at birth is 78.7 years in 2011; 81.1 years for US women; and 76.3 years for US men (Hoyert and Xu, 2012). The difference in life expectancy between men and women, now just under 5 years, has been declining since 1979, when the gap was nearly 8 years. There is a persistent racial gap in life expectancy as well, blacks have life expectancy of 75.3 in 2011 compared with 79.0 for whites.

More important as an indicator of late life health, however, is the life expectancy at age 65. For the total US population, life expectancy at age 65 has increased from 17.2 years in 1990 to 19.2 years in 2009 (Arias, 2012). White women have the longest expected survival, 20.3 years and black men the shortest, 15.8 years. In 2009 for the first time life expectancy at age 75 exceeds 10 years for all demographic groups, men and women, whites and blacks.

These gains in life expectancy reflect improvements in the underlying age-specific mortality rates. Between 1935 and 2010 death rates for persons aged between 65 and 74 fell by 62% (Hoyert, 2012). In the most recent decade, 2000 to 2010, the largest reductions in mortality occurred for males, with non-Hispanic black men experiencing the largest declines. All three major causes of death, heart disease, cancer, and stroke showed declines (Minino, 2013). Of growing importance for later-life health is the significance of Alzheimer's disease (AD) as a cause of death. Mortality from AD has steadily increased during the last 30 years, becoming the fifth leading cause of death for people aged 65 and over (Tejada-Vera, 2013). Alzheimer's disease accounts for between 5 and 15% of all deaths in older people. Some of this increase is due misclassification of AD into other categories leading to a significant undercounting of deaths attributable to AD. Changes in the coding of cause of death, in place since 1999, have allowed for estimation of a more consistent trend (Moschetti et al., 2012). Since Alzheimer's disease is often preceded by many years of disability, the impact of this increase on health care and family costs is an important consideration for the future.

Disability and Functioning

Since disability is a major driver of health and personal care costs, tremendous effort in recent years has been expended on describing and documenting trends in disability levels in the older population. Disability is most often defined relative to the ability to live independently and take care of one's personal care needs. The inability to perform the most basic activities, referred to as activities of daily living (ADLs), is considered the most severe form of disability. This standard set of activities includes bathing, dressing, eating, toileting, transferring from bed and chairs, and walking around inside. Less severe disability is measured by the inability to perform instrumental activities of daily living (IADLs), routine household tasks shopping, cleaning, cooking, and going places.

In his earlier discussion, Manton (2001) describes the US declines in functional disability first documented in the 1982 to 1989 National Long Term Care Surveys (NLTCS). The NLTCS are sets of longitudinally related surveys designed to assess changes in functional status, social conditions, and Medicare and LTC service use in the US elderly population. Through the 1990s, other US population studies found even larger declines than that first reported by Manton et al. (1997). Freedman and Martin (1998) using the 1991–1996 Survey of Income and Program Participation reported a decline which existed at the higher levels of disability and at advanced (85+) ages. Waidmann and Liu (1998) also found confirmation of declines in the 1993–1996 Current Medicare Beneficiary Survey. Crimmins et al. (1997) found evidence for declines in the 1984 Supplement on Aging and the LSOA (longitudinal study of aging) from 1986 to 1990. Evidence of declines has been found in the 1985 and 1995 Supplements on Aging to the National Health Interview Survey (Crimmins and Saito, 2000). Evidence for declines in European countries was found in Waidmann and Manton (1998).

These various studies, while finding relatively consistent evidence of declines in limitations in IADLs and in functional limitations, produced mixed results on the trend in the most severe type of disability, limitations in ADLs. In an effort to summarize and harmonize the results of these studies a technical working group was formed in 2002, drawing together researchers with experience from five national data sets covering the US population: the Health and Retirement Study (HRS), the Medicare Current Beneficiary Survey (MCBS), the NHIS, the National Long Term Care Survey (NLTCS), and the Supplements on Aging (SOAs). The working group concluded that while evidence of a decline in activity limitations was mixed in the 1980s, by the mid-1990s there was a clear downward trend in reported limitations across surveys, despite differences in question wording and study design (Freedman et al., 2004). While this trend was most pronounced in limitations in

IADLs and in functional limitations, from the mid- to late 1990s the proportion of the older population reporting difficulty in performing ADLs declined steadily, too.

This promising news, described as one of the most significant advances in the health and well-being of Americans in the past quarter-century (Schoeni et al., 2008), has been tempered by more recent evidence. In the most recent decades, since 2000, these trends appear to be changing. A recent summary (Freedman et al., 2013), carried out by many of the same researchers involved in the technical working group, compares results from four of the same national data sets covering the US population with the substitution of the National Health and Nutrition Examination Survey (NHANES) for the SOAs. All of these surveys cover the period 2000–08 and the NLTCS and MCBS allow analysis of both community and institutional populations. Carefully controlling for differences in question wording, coverage, and coding, trends in ADL and IADL limitations were estimated from each study. In contrast to the steady downward trend observed in the 1980s and 1990s, the more recent years of data show no change in the proportion of the older population reporting difficulty in performing these personal care and household activities.

More alarming than the apparent stalling in improvement in functioning at older ages is evidence that health at younger ages, those aged 50–64, is not improving and, perhaps, declining. Analysis of the NHIS (Lakdawalla et al., 2004) found that between 1984 and 1996 there was an increase in needs for help among those in middle age, although the numbers were small. Using the Behavioral Risk Factor Surveillance Survey (BRFSS), Zack et al. (2004) found an increase from 1993 to 2001 in those in middle age reporting poor or fair health. Worsening functioning and health were observed from 1992 to 2004 in the HRS (Soldo et al., 2007) for younger cohorts. Examining a variety of health measures, Martin et al. (2009) conclude that trends for the Baby Boom generation vary by measure, period, and age group. For mortality and self-reported health, baby boomers are doing better, while trends for functional limitations and the need for IADL help are stable. Other analyses find that the proportion of people aged 50–64 who report needing help with personal care, while small, increased between 1997 and 2007 (Martin et al., 2010b).

Disease Prevalence

During the period while mortality rates were falling and disability was clearly declining, prior to 2000, the prevalence of most chronic diseases increased. Between 1984 and 1994 increases in self-reports of arthritis, heart disease, cancer, diabetes, stroke, and osteoporosis were observed in the population aged 70 and older (Crimmins and Saito, 2000; Freedman and Martin, 2000). Manton et al. (1995) observed that some conditions decreased from the 1980s to the 1990s (arthritis, circulatory, and cerebrovascular conditions), while others increased (pneumonia, bronchitis, and diabetes).

In more recent time periods, after 2000, the prevalence of chronic diseases continued to increase in the older population. Importantly, musculoskeletal conditions, like arthritis, which have strong links to functional impairments and disability have shown increases. During the time period, 1997–2004, continuing increases in the prevalence of arthritis, cancer, diabetes were reported in the NHIS, although no significant change was observed for heart disease, stroke, or lung conditions (Freedman et al., 2007). This trend is observed in younger cohorts, too. Among those aged 50–64 an increase in musculoskeletal conditions are the most commonly cited causes of disability (Martin et al., 2010b). Unclear is the effect of cognitive impairments on the disability trends. While the prevalence of Alzheimer's disease has increased, the contribution of this condition to overall disability is harder to measure in our large national surveys due to proxy respondents and the greater likelihood of institutionalization.

Not only has chronic disease prevalence increased, but the likelihood of reporting two or more chronic conditions has increased in recent years. Analysis of data from the NHIS shows that among those aged 65 and over the proportion of those reporting two or more chronic conditions (defined as hypertension, heart disease, diabetes, cancer, stroke, chronic bronchitis, emphysema, asthma, or kidney disease) increased from 37 to 45% between 2000 and 2010 (Fried et al., 2012). The most common combination was hypertension and heart disease (21%) but one of the biggest increases was seen in the percentage with both hypertension and diabetes; an increase from 9 to 15% over the 10-year period. These increases occurred for both men and women and for all racial groups.

Causes of Disability Trends

The reasons for the decline in disability observed during the close of the twentieth century and the reasons for the more recent stagnation in improvement remain unclear. The increased prevalence of chronic diseases in tandem with disability declines indicates some possible explanations (Schoeni et al., 2008). One theory is that the earlier diagnosis of chronic conditions has led to higher disease prevalence at a stage before impairments are evident. Furthermore, earlier treatment of chronic conditions may postpone the debilitating effects of the disease. Better medical treatments and improved drug therapies may make diseases less disabling.

The use of assistive devices and accommodations is another possible explanation for the seeming paradox of increased disease and decreased disability. To the extent that disability is a function of both personal abilities and the environmental context in which activities are performed, changes in the environment alone may reduce reported disability. The IADLs, which saw the largest decline, could have been influenced by changes in the socioeconomic environment which allow changes in socially defined gender roles (e.g., men doing more grocery shopping or laundry).

The reversal of the trend in disability improvement is very new and likely to engage the attention of researchers in the coming decade. Trends in obesity are often cited as a primary driver of the reversal and may operate through diabetes, arthritis, and heart conditions (Sturm et al., 2004), but others attribute less of the increase directly to obesity (Martin et al., 2010a). The past improvements may have reflected a change in the disablement process, particularly the use of technology

and assistive devices (Schoeni et al., 2008). Future declines in disability may require even newer technologies if we have reached a saturation of the use of these devices or run up to the limits of their ability to compensate for functional changes. The lack of health improvements in the cohorts soon to reach advanced age, coupled with the larger size of these age cohorts, may signal a costly reversal of past trends in the older populations need for care.

Aging and Memory

Lars-Göran Nilsson, Stockholm Brain Institute, Stockholm University, Stockholm, Sweden

Abstract

This article first summarizes the current state of the art regarding research on how five different memory systems change as a function of age. These systems are procedural memory, perceptual representation system, semantic memory, working memory, and episodic memory. Working memory and, especially, episodic memory are the memory systems most affected by increasing age. The second part of the article deals with two types of data that have been used as the basis for theorizing about aging and memory. These are cross-sectional data and longitudinal data. Most of the data that have been collected so far in this field of research are cross-sectional data. It is claimed in this article that such data say very little about the individual development of memory in adulthood and old age. It is claimed that most of the variance in such data are due to cohort differences rather than to the development of memory. The third part of the article is about the large variability in performance in the aging population. Most of the research in aging and memory has conceived of the aging population as a homogeneous group and typically just means and standard deviations for the whole group have been reported. Recent research, however, has demonstrated that there is much important information to be gained when considering subgroups of the whole age group. Three such subgroups have been suggested as one possibility. These three groups are decliners, average, and maintainers. Future research will demonstrate whether there are other subdivisions that are more appropriate.

Research on aging and memory has increased enormously in amount and quality during the last few decades. According to Web of Science, regarding the quantity of contributions, there were six papers published in this field in 1970, 14 in 1980, 83 in 1990, 1797 in 2000, and 5381 in 2010. A major reason for this development is, of course, that researchers in this field have come to realize that there are many important issues to cover, not only because of the benefit for the aging individuals themselves, but also for the society in general in taking care of the aging population. Additionally, researchers are, of course, also interested in obtaining knowledge growth in an interdisciplinary sense about the underlying features of individual development and decline in cognitive processing in adulthood and old age.

There is a large variability in cognitive functioning in old age. Some old people show no or very little cognitive decline and continue a life up to very old age in what can be characterized as successful aging (Rowe and Kahn, 1987). Others remain stable in cognitive functioning at an average level up to old age, and then there is a decline in performance sometimes leading to dementia or other forms of neurodegenerative disorders. Still others start to show cognitive decline relatively early and will eventually develop signs of dementia and some will get the dementia diagnosis.

An issue that has been brought up in recent years on the research agenda in research laboratories is when age-related cognitive decline begins (e.g., Salthouse, 2009). Is dementia inevitable is another question that has started to be discussed in the literature (e.g., Gondo et al., 2014). Still another question in this research is whether cognitive signs and biological markers can be found early in life for persons who later will develop dementia (e.g., Nilsson, 2014). The general question here is of great societal interest as to whether psychological and medical treatments can be offered to these people, who show early signs as risk factors for dementia long before diagnosis of dementia. In hopeful quarters, the time of detection of early markers is the critical factor for the success of treatment. When the dementia development has gone on too long and a person has been diagnosed as demented, it is too late. The degeneration has gone too far and the existing treatments are not of much use. These and other issues are intensively studied in many laboratories around the world at present, contributing to the great increase in the number of published papers in this field. The present article will cover some of these domains of research.

The most primary research areas in the literature previously covered how different memory systems develop and age differently, and how different cognitive domains differ in sensitivity in detecting a decline in performance. These issues are still of great interest in the scientific community. However, in recent years, there has been a change in focus of this research. Previous research was focused on the theoretical emphasis on the development of different memory systems and cognitive domains for the sake of interdisciplinary knowledge growth, whereas recent years of research in this general field have also been keen on providing solid data on early signs of dementia and other neurodegenerative diseases for a possible application of research to individuals, who are at risk for dementia and possible treatments, and for the sake of society and the costs for societies, when life expectancy increases in most countries around the world and more and more people become demented or acquire other neurodegenerative disorders. One important reason for this development is, thus, that life expectancy is increasing in most countries in the world, partly because of improvements of health care in these countries, and an increased awareness that people can affect their own life expectancy by a healthy life style including concerns about exercise, social networks, intellectual activities, and engagement in what is happening in their close surroundings with relatives and friends and more generally in the surrounding world.

Another general change in research in this field of science has been the insight from many researchers that cross-sectional data are not optimal when trying to explore the development of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.51045-9

cognitive aging across the life span (e.g., Nilsson et al., 2009; Schaie, 2009). Instead, it is argued among many that longitudinal studies should be conducted, since cross-sectional studies are primarily picking up cohort differences among participants in such studies. There are also difficulties with longitudinal studies (e.g., test–retest effects and attrition effects). However, these effects can be accounted for and controlled in carefully planned longitudinal studies (e.g., Josefsson et al., 2012; Rönnlund et al., 2005).

Still another new orientation of the research on aging and memory is the interest in trying to combine classical research on cognitive psychology, with research on brain imaging and the role of genetics for understanding how memory, and cognition in general, changes as people become older.

As already mentioned, there has also been an increasing interest in recent years in this research field to take into account the great variability in performance in memory tasks and in cognitive tasks in general, especially so when observing that this variability increases with age. Previously, means and standard deviations were presented, without any closer interest in what the variability in performance across the life span might mean. As argued by many researchers (e.g., Baltes, 1968; Schaie, 1996) for a long time, this variability in performance might carry considerable important information about the development of memory and other cognitive functions across the life span. For example, as some researchers have tried, is it of interest to study whether people develop differently, when they are classified as average in performance, performing at a higher level than average, or performing at a lower level than the average participant in a study. Although this classification of participants is crude, it may carry important information about variables related to each of these categories of participants in a study of aging and memory.

Outline of the Article

Following the traditional presentation of the state of the art of research on aging and memory, I will continue with a section on the difference in results shown in cross-sectional studies and longitudinal studies in research on aging and memory. Closely related to this is the topic of the great variability in performance on memory tasks and cognitive tasks in general.

State of the Art Regarding Current Knowledge on Memory Systems and Cognitive Functioning in Relation to Age

In a seminal paper, Bäckman et al. (2001) described the state of the art of knowledge on this topic. The essence of this article was that different memory systems, according to the terminology proposed by Tulving (1983), age at different rates.

The oldest memory system, according to Tulving (1983), both phylogenetically and ontogenetically, is procedural memory. This memory system is responsible for well-acquired motoric abilities like walking, dancing, swimming, bicycling, and brushing teeth. In general, it is about the acquisition of motor, perceptual, or cognitive abilities. These abilities develop gradually as an effect of practice (Nyberg and Tulving, 1996). This memory system does not age in the same way as other memory systems when persons grow older. If you have learned to go on a bicycle, or to swim, you will never forget this. To the best of my knowledge, there is nothing in the recent literature that has provided evidence for a change in this view. It should be acknowledged though that surprisingly little research has been conducted regarding how this memory system develops as a function of age.

The next memory system in Tulving's terminology is that of perceptual representation system (PRS). This memory system is generally responsible for navigating in the surrounding world. In the laboratory, this system is usually tested by means of word fragment completion tasks or word stem completion tasks. In a word-fragment completion task, participants are first presented with a list of words and asked to classify these, for example, as abstract or concrete words. Nothing is said in the instructions about a forthcoming memory test. Usually after having completed some other cognitive tasks, the experimenter returns to this task and tells the participant that he/she will now see fragments of the words that were shown previously. The task of the participant is to say the first word that comes to mind when each fragment is shown. Interestingly, participants manage this task very well independently of whether they are brain injured or healthy. If, however, the experimenter instead says that the task of the participant is to use the fragment presented as a cue to remember each word that was previously presented, the result pattern changes dramatically. Participants with a brain injury or some other brain disorder (e.g., dementia) do not manage the task at all, whereas healthy controls manage it quite well. In this latter task, participants are demanded by the instructions to use a conscious recollection of a previous episode, i.e., the previous presentation of the list of words. Brain-damaged people fail this task, whereas healthy people manage it reasonably well. This basic finding appears still to hold true. In addition to priming tasks (e.g., word fragment completion and word stem completion tasks), a fair amount of research on this topic of age differences in PRS has been conducted using a paradigm that aim at differentiating an automatic component of implicit retrieval and another component of controlled, deliberate, and explicit retrieval (Jacoby, 1991). Several researchers, who have used this procedure in cognitive aging studies (e.g., Jennings and Jacoby, 1993; Titov and Knight, 1997), have demonstrated a significant age-related deficit in the controlled, explicit retrieval component together with no age differences in the automatic, implicit component. In another experimental paradigm developed by Gardiner and Java (1993), the basic aim was the same, namely, to differentiate between the contribution of a component that is based on conscious recollection of a previously encountered event (these responses are called 'remember' responses) and other responses that are not consciously recalled from a previous event, but rather merely recalled on the basis of the participants having a feeling of familiarity of the event (these responses are usually referred to as 'know' responses in this paradigm). Research has been reported that age differences are substantial for remember responses, but minimal and nonsignificant for know responses (e.g., Mäntylä, 1993).

A third memory system in Tulving's terminology is semantic memory. This system is about general knowledge, e.g., what is the chemical designation of regular table salt?, or what is the

capital of Spain?, or what is the opposite of warm? There is a general consensus in this literature that there is no evidence available for a lower performance of such general knowledge tasks for older than for younger participants. Going all the way back to the time when the term semantic memory was coined (Collins and Quillian, 1969; Collins and Loftus, 1975; Quillian, 1966), there has been a basic assumption that the basis for this memory system is an internal lexicon. It is furthermore assumed that this lexicon is organized hierarchically in a top-down structure with concepts, terms, words, and associations in networks of nodes at different levels. At a top level, one category might be 'flowers,' with wild flowers and garden flowers, respectively, at a lower level. At still another lower level flowers may be categorized as red flowers or yellow flowers. At still another lower level both rose and tulip might be represented as red flowers according to one categorization and yellow flowers according to another possible categorization.

With regard to cognitive aging, nice and convincing data were presented by Laver and Burke (1993) that the internal lexicon remains stable across the life span. Young and old individuals are quite similar in the word associations they generate, they access categorical associations in a similar way, and vocabulary scores remain stable or even increase as a function of age at least until very late in old age (see Bäckman and Nilsson, 1996; for an overview). However, there are reports of age differences, such that older people have greater difficulties in word-finding tasks, e.g., proper names (e.g., Crook and West, 1990), and generating items in tasks of word fluency (e.g., Bäckman and Nilsson, 1996). This finding by Bäckman and Nilsson (1996) brings about the question of to what extent cognitive tasks usually used in this research are process pure. When this study was conducted some 20 years ago (Bäckman and Nilsson, 1996), fluency tests, even letter-fluency tasks, were regarded as adequate tasks to assess semantic memory. Later, however, such letter-fluency tasks have come to be regarded as tasks measuring working memory and executive functions. This has been shown by means of brain imaging techniques showing frontal lobe activity when generating words in a letter-fluency task.

A fourth memory system is working memory. This system was previously called short-term memory or primary memory. Baddeley and Hitch (1974) and Baddeley (1986) coined the term working memory to include not only the passive maintenance of information in mind, but also the more active processing of information in working memory, including executive functioning like planning, switching, and updating. Brain imaging studies have demonstrated that prefrontal regions of the brain are typically activated when participants are solving working-memory tasks (see Cabeza and Nyberg, 2000; for a review). Working memory performance does not in general show any age differences when the task demands are simple like maintaining information in memory (e.g., Corey-Bloom et al., 1996; Gregoire and Van der Linden, 1997). However, as the cognitive demands increase in the tasks used to assess working memory, involving more executive functioning, older participants show a lower performance than younger participants. This relationship was convincingly demonstrated in an early meta-analysis by Verhagen et al. (1993). When the task requires simultaneous storage and processing of information, age differences are in general robust (e.g., Brébion et al., 1995). This conclusion seems to hold true even today (e.g., de Frias et al., 2005, 2010). These findings suggest that working memory is not a unitary concept. Neural support for such a conclusion was reported by Rypma and D'Esposito (2000), when demonstrating no age-related differences in the ventrolateral prefrontal cortex during working memory performance, although there were age-related decreases in the dorsolateral prefrontal cortex.

Episodic memory is the fifth memory system according to Tulving's (1983) terminology. This memory system deals with encoding and retrieval of information in a certain context of time and place. According to Tulving, it is the youngest memory system, both phylogenetically and ontogenetically. Episodic memory is easily and strongly affected by many variables, including age (Nilsson et al., 1997). Episodic memory is different from other memory systems in that it requires a conscious recollection of a particular study episode and it has been suggested that it is this conscious travel backward in time that makes it so vulnerable for a decrement in performance as a function of age.

In trying to explain the age differences in episodic memory that have been empirically demonstrated, several different approaches have been attempted. Early in the history of cognitive aging research, age-related differences involved references to specific memory processes operationalized by the experimental paradigms used (e.g., levels of processing, organization, elaboration). This research and these theoretical attempts were nicely reviewed by Craik (1977; Craik and Jennings, 1992). It was often claimed that old persons show a lower performance than young persons, because they fail in spontaneously adopting a deep semantic encoding, or they do not organize the to-be-remembered materials as efficiently as young persons. Such process-oriented explanations are still proposed in research articles in the field every now and then. However, soon a different approach was attempted in trying to explain the observed age differences in episodic memory tasks. More general constructs were proposed to be the reason for memory deficits in old age. Processing speed was one such construct that was proposed. It was claimed that cognitive processing gets slower as people become older. Salthouse (1996) was probably the most pronounced advocate for this view. Salthouse and his collaborators published several papers in support of this view. Others have argued against this view and the discussion is still going on. For example, Sternäng et al. (2008) argued that this view may hold for cross-sectional data, but does not hold for data based on narrow-cohort age designs or longitudinal designs.

Working memory capacity is another general construct suggested to be responsible for a declining performance level as a function of age of participants in studies trying to find an explanation for age differences in episodic memory. It has been demonstrated that statistical control of working memory capacity attenuates or even eliminates age-related differences in episodic memory using a correlational approach rather than an experimental approach (Hultsch et al., 1998). This meditational approach of explaining age differences in episodic memory has certainly been refreshing the understanding of age differences in episodic memory and potential explanations of these. However, it has also been

claimed (e.g., Zacks et al., 1999) that the links between these constructs and performance in complex episodic memory tasks are as of yet relatively poorly understood. More research is needed regarding these links to episodic memory in order to reach consensus about the reasons for these age differences. Recently, Del Missier et al. (2013) presented a new approach to examine the relationship between working memory and episodic memory.

Still another approach to explain the age differences in episodic memory is based on the assumption that there are multiple conditions with effects on brain functioning that could be involved. Among these conditions are demographic factors, lifestyle factors, health-related factors, and genetic factors that might influence episodic memory performance with main effects or in interactions. This approach to an understanding of age differences in episodic memory is a very complex one. It is not at all understood how these factors might interact. These factors are presently being explored in many studies with respect to main effects of each individual factor. Progress is being made, but when evaluating the empirical results, one should be cautious in interpretation, because the influences of interactions may completely invalidate the interpretation of the results.

With respect to demographic variables affecting episodic performance in late life, education and sex are two very important factors. Regarding education, several studies have shown that there is a strong relationship to memory performance. In one relatively recent study, we (Habib et al., 2007) demonstrated that education is the single most important factor characterizing individuals, who we classified as successfully aged on the basis of cognitive performance in a large test battery. We used the number of years in formal education as a measure of the education attained. We realize that this is a very crude measure that does not take into account, the quality of the schooling and it does not take into account the preparation for this schooling for each individual pupil when starting school. It would be interesting to have early data available of grades or evaluations by teachers about the intellectual level of each individual pupil, who become a participant in a longitudinal study on aging and memory covering a large section of the life span. Such data could serve many purposes. For example, such data could serve as an important starting point for what the intellectual level is before further development in school, university, and professional life. To the best of my knowledge, no study on cognitive aging has reported such data. However, the collection of such data is in progress within a longitudinal study on memory, aging, and health, called the Betula Study (Nilsson et al., 1997, 2004, 2006).

Sex is also a demographic variable that has a strong effect on episodic memory performance. It has been demonstrated in many studies that there is a female superiority in episodic memory performance (e.g., Herlitz et al., 1997). Both biological factors (e.g., Collaer and Hines, 1995) and social factors (Eagly and Wood, 1999) have been proposed, but there is still no consensus in the research literature about which is the most likely explanation of this female superiority in episodic memory performance.

Lifestyle factors have also been proposed as a potential explanation for age differences in episodic memory. In general, the picture is that a healthy lifestyle with physical and cognitive exercise is good for cognitive aging (e.g., Christensen et al., 1996) and unhealthy lifestyle with lack of social, cognitive, and physical activities leads to a lower performance in episodic memory tasks (e.g., Pushkar et al., 1999). Substance use has also been examined in relation to cognitive aging, but the picture is quite mixed. When effects of substance use have been found, in general, the effects have been relatively small. Some researchers (e.g., Hill, 1989) have reported negative effects of substance use on cognitive performance, whereas others (e.g., Elias et al., 1999) have found positive effects.

Stress is another factor that has been proposed as a risk factor for cognitive deficits in old age (e.g., Johansson et al., 2010; Norton et al., 2009; Persson and Skoog, 1996). Detrimental effects of stress on cognitive performance have not been found across the board (e.g., Fountoulakis et al., 2011; Motomura et al., 1998). In an ongoing study in our own laboratory with Betula data, we also failed to demonstrate any negative effects of stress (Sundström et al., 2014). The lesson to learn from this is perhaps that the effects of stress, if they exist, are relatively small, the overall picture of data patterns is rather mixed, and perhaps there is a large risk for false positives in many studies.

Cross-Sectional Data versus Longitudinal Data for Exploring Adult Life Development in Cognitive Aging

Except for the enthusiastic and inspiring attempts by Karl W. Schaie to bring this topic forward to an important issue of the research agenda of this field, there are very few other cognitive-aging researchers, who have brought up this for discussion. In recent years, many researchers have realized the importance of Schaie's claim that longitudinal data are what is needed, when the research question is to seek to understand how individuals develop cognitively in adulthood and old age.

Schaie's basic claim was that there are pros and cons with all research designs (cross-sectional or longitudinal). It should be noted already here that the majority of the studies that have been carried out on aging and memory are cross-sectional in design. Relatively few studies published in this area have used a longitudinal design. It will be argued here that cross-sectional designs primarily pick up cohort effects, when comparing old individuals who perhaps were born in the beginning of the twentieth century with those who were born in the middle of the twentieth century or even later. Some studies can illustrate excellently what these cohort differences are contributing to how these individuals are doing cognitively, when tested several years later. In two recent studies, we have demonstrated how cognitive functions change across generations as a result of cohort differences (Rönnlund and Nilsson, 2006, 2009). In these two studies, we demonstrated that these so-called Flynn effects (Flynn, 1984, 1987) could be attributed to three factors: nutrition, education, and sibship size. These factors accounted for almost all variance in performances on episodic memory, semantic memory, and visuospatial ability. Nutrition (with body height as a proxy), education (with number of years in formal schooling as a proxy), and sibship size (number of siblings in the family was used as a proxy) accounted for

99.6% of the variance in episodic memory tasks, 99.9% of the variance in semantic memory tasks, and 94.6% of the variance in tasks of visuospatial ability.

We have examined performance in episodic memory tasks and semantic memory tasks in one study (Rönnlund et al., 2005), in another study on performance in a Tower of Hanoi task (Rönnlund et al., 2008), and on performance in a visuospatial task in still another study (Rönnlund and Nilsson, 2006) by comparing the data patterns when using a cross-sectional design and when using a longitudinal design. The data we used in these two studies emanate from a longitudinal, cohort study on memory, health, and aging. The study has been going on since 1988, with a total of about 4500 participants, some of whom have been tested six times, 5 years in between test occasions; some have been tested five times; participants in one sample have been tested three times; and the participants of three samples have been tested once (Nilsson et al., 1997, 2004, 2006). Participants have been selected randomly from the population registry of the city of Umeå in northern Sweden. Data for about 2000 variables each time a participant is tested are collected. These variables include an extensive cognitive test battery; a thorough health examination, including blood and saliva sampling; and a series of questionnaires on demographic variables, health history for the participant, parents and siblings to the participant, medication, leisure activities, exercise, and social networks of the participants. From the blood sampling, we extract DNA and have typed for several genes in a candidate gene approach, and for two large-scale genome-wide association studies. We are also doing functional magnetic brain imaging (MRI) and structural MRI on a subsample of about 367 participants (Nyberg et al., 2010).

To illustrate the differences in data patterns in cross-sectional and longitudinal analyses, the study by Rönnlund et al. (2005) will briefly be summarized.

Needless to say, the data from these two designs look quite different. An example of this on the basis of data from Rönnlund et al. (2005) is given in **Figures 1** and **2**. As can be seen from the cross-sectional data presented in **Figure 1**, the decrease in performance for episodic memory from the age of 35 years to the age of 85 years is approximately linear. This linear pattern has also been observed in several other cross-sectional studies (e.g., Schaie, 1996; Park et al., 2002), and in some cases, the decrease in performance has been observed to start as early as at 20 years of age.

Based on the same participants in the Betula Study, longitudinal data for the same episodic memory tasks are presented in **Figure 2**. As can be seen, the data pattern is radically different as compared to the cross-sectional data.

The longitudinal time frame of these data is 10 years measured at three points. In the longitudinal data, control has been made for attrition effects and test–retest effects by means of subtracting the gain in performance, when participants are tested a second or a third time. The size of this gain can be estimated by comparing the performance when participants are tested the first time and when they are tested for the second or the third time. For example, at T3, participants in S4 are tested the first time, whereas participants in S2 and S3 are tested the second time, and participants in S1 are tested for the third time. Thus, when doing this type of control for longitudinal data, the decline in episodic

Figure 1 Estimated memory changes across age (T scores) for episodic and semantic memory on the basis of cross-sectional data. Stability, growth, and decline in adult life-span development of declarative memory: cross-sectional and longitudinal data from a population-based sample. Psychology and Aging 20, 3–18.

Figure 2 Estimated memory change across age (T scores) for the episodic and the semantic factors on the basis of practice-adjusted longitudinal data. Reproduced with permission from Figure 3 in Rönnlund, M., Nyberg, L., Bäckman, L., Nilsson, L.-G., 2005. Stability, growth, and decline in adult life-span development of declarative memory: cross-sectional and longitudinal data from a population-based sample. Psychology and Aging 20, 3–18.

memory performance is not observed until much later as compared to that in the cross-sectional data. Salthouse (2009) has argued that lack of power typically seen in longitudinal studies is a serious concern for such studies, but the time-related improvements seen in such studies when participants are tested a second or a third time are clearly difficult to reconcile with cross-sectional data (Rönnlund et al., 2005).

It should also be mentioned in this context that there are differences in brain-imaging data between cross-sectional and longitudinal analyses as in the behavioral data just described. It has been consensus in this field for quite some time that increased brain activity in the frontal lobes is associated with increasing age of the participants. The mechanism for this has been believed to be compensation. As people in such studies grow older, they start using the frontal lobes in both hemispheres, whereas young subjects use the frontal lobes in one hemisphere for the same task. In these earlier studies, a cross-sectional design has been used. In a recent study (Nyberg et al., 2010), we also found such a data pattern when we used a cross-sectional design. However, when we analyzed the data by means of a longitudinal design, we found that the activity in the frontal lobes decreased with increasing age. When analyzing the cross-sectional data closer, we found that the increase in frontal lobe activity was due to cohort effects. The increase in this activity only occurred in subjects with high education. However, in the longitudinal analyses, the frontal lobe activity even for these subjects decreased with increasing age.

In summary, the data presented here, both behavioral and functional brain-imaging data, show that cross-sectional results and longitudinal results are very different. When cohort differences, test–retest effects, and attrition are controlled for, longitudinal data give a more valid picture of the individual development of cognitive function in adulthood and old age than cross-sectional data, which generally are contaminated by cohort differences.

Large Variability in Cognitive Performance in the Aging Population

In most of the previous studies on aging and memory, different age groups have been treated as they are relatively homogeneous in the cognitive status within each age cohort. A mean for each age group and a standard deviation have been reported for each age cohort, usually based on cross-sectional data. Sometimes, it has been noted that the standard deviation is larger for the older groups, but most often this information has been left without comments.

In a recent paper, we defined three groups of participants (Josefsson et al., 2012) about this variability in cognitive performance among old people. They referred to those who were performing very well as successfully aged, those who were average, and those who were decliners. This is a new interesting concept in the area of cognitive aging and it is expected to expand.

In cross-sectional studies, the identification of individuals to different groups (e.g., decliners, average, maintainers)

Figure 3 (a) Average test scores for 1558 participants: maintainers, average performers, and decliners. Missing values after dropout are predicted using individual baseline test score and average slope for the memory performance group they belong to. (b) Comparison of predicted episodic memory score at year 15 for complete cases, with and without attrition correction. Reproduced with permission from Figure 1 in Josefsson, M., de Luna, X., Pudas, S., Nilsson, L.-G., Nyberg, L., 2012. Genetic and lifestyle predictors of 15-year longitudinal change in episodic memory. Journal of American Geriatric Society (JAGS) 60, 2308–2312. doi:10.1111/jgs.1200.

misses the point of examining the extent to which the persons have preserved their performance in the same group or whether they have changed to another group, for example, whether a person in the declining group has decreased in performance from the average group. Longitudinal studies, on the other hand, offer a direct assessment of preserved or changed functioning (Josefsson et al., 2012). In this article by Josefsson et al., we divided the participants into three groups (decliners, average, maintainers). The data pattern for these three groups is presented in **Figure 3(a)**.

However, a difficulty of great concern in longitudinal studies is how to deal with attrition. In previous longitudinal studies, it has been assumed that attrition is random. There is evidence that attrition causes bias (Cooney et al., 1988; Habib et al., 2007; Yaffe et al., 2009) because those who remain in the study typically show better cognitive performance at baseline than those who drop out. When participants with a faster decline drop out earlier than those who maintain their performance and remain in the study, attrition is not random and cannot be ignored. The paper by Josefsson et al. (2012) has proposed a statistical model showing how to account for attrition in longitudinal research. **Figure 3(b)** depicts the difference between attrition-corrected data and complete cases using this method.

Final Remarks

Aging and memory is a very active area of research. Much progress has been made, although the findings from earlier studies on the effect of aging on separate memory systems and separate cognitive functions are still holding up. The new and interesting twist to this research area is the interest it has gained from neuroscientific approaches, including research on brain imaging and genetic trends. Much new news is to be seen in the field in the future integrating cognitive psychology, neuropsychology, brain imaging, and genetic analyses in studies we can see ahead.

Abstract

This article summarizes the interests of and perspectives taken in the geographical study of aging. Dealing first with research engagements with space and then with place, the article concludes by highlighting some important and emerging areas of critical inquiry both in terms of theoretical and empirical interests.

Introduction

The geography of aging is an established field of academic scholarship focused on the spatial aspects of age and aging. Although broad and multidisciplinary in its composition – involving, for example, sociology, environmental psychology, demography, migration studies, urban planning and architecture, nursing, and other professionally focused research – its primary/core disciplines are human geography and social gerontology, hence the increasingly used title '*geographical gerontology*' (i.e., gerontology done geographically) and the lesser used alternative '*gerontological geography*' (i.e., geography done gerontologically). Indeed, these two disciplines have informed the field greatly in terms of its evolving empirical interests and theoretical and methodological innovations for over 40 years (see Andrews et al., 2007, 2009).

One potential reason for the continued and arguably increasing interest in the geography of aging in recent years has been a 'spatial turn' across both the health and social sciences (Andrews et al., 2013). Indeed, while the spatial turn in the social sciences has been theoretically primed by a desire to understand how humans are 'emplaced' in the world around them and the consequences of their presence (i.e., the interweaving of social, psychological, and physical life), the spatial turn in the health sciences has been associated with the increasing importance of the social model of health (i.e., an acknowledgment that health and well-being are strongly rooted in factors that lie outside the production and consumption of medicine, in communities and the broader environment). This said, however, of note is a limited yet significant critique emerging from within human geography itself on the whole idea of the geography of aging. This is based on dissatisfaction with a perceived disproportionate attention attributed in the parent discipline to people and populations at the extreme chronological ends of the human age-spectrum. Hence, as an alternative, certain scholars have promoted the 'relational geographies of age' which, rather than focusing on single demographic cohorts, would instead focus on intergenerationality and lifecourse to help illuminate, more fully, the meaning of age in relation to a greater number of people and situations (Hopkins and Pain, 2007). Although these arguments have gained traction among certain geographers, they have not been powerful or accepted enough to restrict the continued expansion and development of the geography of aging as an academic field; a majority of scholars have recognized that older people and populations have distinct characteristics, challenges, and circumstances that are distinctly geographical in nature and demand dedicated academic consideration (Andrews et al., 2007).

Space and Older People

At one level, drawing on a positivistic 'spatial science' philosophical tradition, space has been understood in the geography of aging as an underlying stage for human agency – an isotropic surface on top of which life plays out. While this understanding might portray an image of space itself as relatively abstract and neutral, when 'things' are located in space, such as older people, facilities and services for them or political boundaries that affect them it becomes more obvious how space might represent substantial features of, and challenges in life (Andrews et al., 2013). This is because space thereafter becomes mathematically distinguishable. *At* the points where things are located, rates, volumes, and other measures emerge and become calculable. *Between* these points, times, distances, movements, and differences do also. The assumption behind thinking about space in this way is that older age has fundamental, underlying, collective geometrical patterns that can be discovered and represented (Andrews et al., 2013).

Based on these understandings, research in the geography of aging has been able to trace how older people are positioned in and move across space, for example, in a substantial volume of demographic and migration research focused at subnational, national (Moore et al., 1997), and international (Kinsella and Velkoff, 2001) scales, and also between them. Notably, not only are older people themselves mapped across space, so are their circumstances and qualities, perhaps the most frequent being their life expectancy, health events, and status. This, for example, has been undertaken at global, continental (Warnes, 1999), and subnational (Pickle et al., 1996) levels, particularly in relation to social intersectionality (variables such as ethnicity, gender, affluence, and access to health and social care). Indeed, more generally within this tradition, scholars have identified the spatial patterning and characteristics of demographic transitions, including declining fertility (due to social change) and increasing life expectancy (due to improvements in diet, living conditions, and healthcare) that underpin demographic aging in particular areas. Notably, although much research here is published in academic

journals, its broad public and policy relevance means that it equally arises as 'gray' literature published widely by governments and NGOs. As Andrews et al. (2013) posit, often in relation to specific policy and administrational contexts, studies have also considered how resources for older people are distributed either by state allocation or by the private sector (Cartier, 2003), often in relation to patterns of utilization (see Nemet and Bailey, 2000). A well-known example of this is research on residential care at national and local scales (Andrews and Phillips, 2002; Ford and Smith, 2008). The motivating belief behind much of this type of research is that it is possible to enhance the spatial design of health and social care systems so that the needs of older people and populations are better met. A utilitarian motivation, which is somewhat idealistic and almost impossible to achieve practically, also emerges here: that where an older person resides should not disadvantage their health, welfare, and longevity – and that state systems should thus work toward the optimum spatial allocations of resources for them.

As Andrews et al. (2013) argue, it would be unwise to classify all of the aforementioned research as a purely 'spatially obsessed' science (a mathematical exercise in mapping for mapping's sake), because treatments of space in gerontology can be far more thoughtful. Indeed, acknowledging the unpredictability and complexity of human behavior, certain research articulates why spatial patterns are not always regular, and/or focuses on the consequences of patterns and/or attempts to critically understand the individual, social, economic, and political processes that drive them. These approaches can be seen, for example, in many of the aforementioned studies of population aging (Davies and James, 2011), the movement of older people (Warnes and Williams, 2006; Newbold, 2008), and services for older people (Rosenberg and Everitt, 2001). Moreover many studies have investigated important social contexts and the consequences of spatial movements; for example, in studies of family networks, the pushes and pulls to and from different locations in migration decision-making and in studies of the outcomes of migrations on individuals, populations, and health and social care systems. Research has considered these issues in the context of short-term and semi-permanent migrations between countries and with respect to short-term and semi-permanent migrations within countries. Notably, a very focused example of an approach that considers the consequences of space can be found in research that builds on studies of the proximity of older people to kin and carers and seeks to understand how the 'challenge of distance' impacts on the nature of personal interactions and relationships (Joseph and Hallman, 1998; Hallman and Joseph, 1999). Indeed, a number of studies here describe the factors that have led to the increasing physical distancing of older people from their adult children, such as social attitudes and economic circumstances. Whatever the reason for increased distancing, this research identifies a decay in immediate interactions and social and care support between families. Studies note though, that distance does not necessarily have to lead to a breakdown of communication between families, highlighting the concept and lived reality of 'intimacy at a distance'.

Also with regard to space, studies have highlighted the substantial challenges that lie ahead for governments and NGOs in meeting even the most basic needs of older populations in developing world countries, which are both growing and aging most rapidly. Indeed, research has highlighted the need for better policies and systems so that care and welfare services are funded and provided to minimum levels and standards. At its most critical, research in this area has also deconstructed globalization processes and the involvement of, and consequences for older individuals and populations (see Harper, 2006). There remains an undeniable 'first-world' bias in much geographical gerontology, a situation that does not reflect the circumstances and needs of the world's aging population (Andrews and Muzumdar, 2010).

Beyond this, other research has understood that space is more dimensional, complex, and problematic than the traditional image of it as a flat surface area. Recognizing instead that space is actively tied to human agency, capacity, and identity, scholars have developed the concept of 'social space' – meaning space as personally used and experienced by older people (Andrews et al., 2013). The idea of social space can be traced in early groundbreaking research by psychologists on environmental press and adaptation (whereby older people, facing physical and mental deterioration and being increasingly challenged by their environment, both reduce their use of space and adjust their relationships to it) (Lawton & Nahemow, 1973). Since these early studies, social space has been taken up far more broadly, now relating to broad-built, social, and other environmental contexts that create particular experiences, opportunities, and challenges for older people (Walsh and O'Shea, 2008; Skinner et al., 2009; Walsh and Gannon, 2011). More specifically, social space is also thought of as space within and between collections of settings that older people frequent and move between in daily, weekly, and monthly rhythms, such as their own homes, their friends' and family members' homes, consumer environments, and formal care environments (Wiles et al., 2009). Meanwhile, at a more intimate level, social space is also about the intricacies of what goes on between people and objects within specific settings, such as health or social care facilities or homes. At one level, the design and functionality of settings is a longstanding research consideration (Barnes, 2002; Gitlin, 2003). At another level, how different groups such as carers, family, and older people connect to, divide, and contest settings is an emerging focus of research (Dyck et al., 2005; Herron and Skinner, 2013). Otherwise, aligning social space with the idea of personal space (the very intimate spatial proximities between people) within settings is considered. These proximities are physical, yet they overlay and impact on interpersonal conversational, emotional, and moral proximities (see Andrews and Peter, 2006).

As described by Andrews et al. (2013), there has been a longstanding research interest in the use of technologies that potentially maintain, recapture, or even extend older peoples' mobility (and thus social space), including vehicles (Rosenbloom, 2001), personal assistive devices, and related interventions (Auger et al., 2010). Underpinning much of this research is a supposition that reduced social space is one factor that contributes to isolation, loneliness, and unhappiness in older age (Scharf and de Jong Gierveld, 2008). Most recently, studies have considered emerging hi/digital technologies and associated systems such as the internet – which compress time

and space as a social and physical barrier for some older people, – leading to what some have termed the 'death of distance' and the creation of replacement 'virtual social spaces' where physical copresence is not a prerequisite to experience and interaction. Of particular concern is how hi-technologies impact upon the form, experiences, and outcomes of older peoples' interpersonal communications and relationships (Milligan et al., 2011). Importantly, this research acknowledges that although some older people have access to, and experience substantial benefits from hi-technologies, others are excluded from them or experience substantial difficulties with their operation (Andrews et al., 2013).

Place and Older People

Places arise, in a very general sense, in much of the aforementioned space-focused research whether they be, for example, particular continents, nations, regions, towns, or settings. Moving beyond such surface engagements however, the facets, processes, and impacts of places have become important research interests in the geography of aging (see Andrews et al., 2013). At one level, a growing interest in place-effects on older peoples' health and welfare has emerged, often at the neighborhood and community level, exploring the impact of social 'composition' on health and welfare (the characteristics of older people in places including affluence, class, and family composition); the impact of social 'context' (the resources available to older people locally such as primary care facilities, various local shops, and services); and the impact of social collectivity (the ways in which people work together and benefit through mobilizing their social capital). At another level, associated with the more humanistic interpretation of space noted above, has been an emerging realization in research that places are much more than coordinates and locations. Indeed, the understanding has developed that peoples' lives unroll in places as complex social and cultural phenomena that are both acted out and felt. It is understood that at one level, because of people and things that occur *in situ*, places possess a basic agency and this agency can be helpful to older people or act as a barrier or challenge. At another level, however, it is understood that underlying this basic agency, far more personal processes are at work. Because of older peoples' experiences of places (the 'embedded knowledge' they gain from frequenting them), places acquire intentionality (i.e., they become about certain things) and essences (i.e., they feel a certain way) (Andrews et al., 2013). Thus, over time, they are ascribed meaning, and might, for example, become centers of attachment. In this way, through these processes places make and affect older people, but at the same time, older people play a part – with other people and things – in the making of places.

Wiles (2005) and later Andrews et al. (2013) summarize how, in line with these ideas, places have been conceptualized in gerontology in six ways. First, as simultaneously physical, social, and symbolic in character, such as a day care facility being subject to design, as social setting, and meaning certain things to society at large. Second, as a process and an essential part of social relationships (including family life and caring relationships). Third, as subject to continued renegotiation, such as when older people move between places or their needs change while in a place. Fourth, as expressing and facilitating power relationships, such as professional hierarchies in clinical settings or intergenerational relationships in home care. Fifth, as fought over and contested, such as between the different groups that occupy a setting where caring takes place. Sixth, as interrelated and interdependent such as a home where care takes place to the neighborhood in which it is located, the neighborhood to a town, and so on.

Andrews et al. (2013) note that across these six categories, the geography of aging has engaged with a wide range of empirical topics. Some issues tackled by recent studies include the role of places in supporting self-regard, self-determination, and self-identity in older age (Hockey et al., 2001; Wiles et al., 2009); the processes behind transnational lifestyles in aging and caring (McHugh and Mings, 1996; Walsh and O'Shea, 2010); the nature and challenges of rurality and aging (Walsh and O'Shea, 2008; Joseph and Skinner, 2012); and urbanicity and aging (Laws, 1993; Walsh and Gannon, 2011). Other well-trodden areas of research inquiry include the dynamics between place and experiences and practices of life and/or caring, particularly in homes and other community settings (Milligan, 2009; Skinner and Joseph, 2011). Given the geographical ideas explicit in them, research attention has also been paid to 'place-based policies' such as 'age-friendly cities' (Plouffe and Kalache, 2010) and, particularly, 'aging-in-place' (Cutchin, 2003; Gilleard et al., 2007; Wiles et al., 2012). Also with regard to place has been a recent engagement with nature and natural landscapes. Drawing on the concept of 'therapeutic landscapes' for example, studies have sought to examine the potentially positive healing and restorative qualities of particular places and activities, such as allotments and gardening (Milligan et al., 2004). Otherwise, with regard to nature, geographers have considered the challenges of weather for older people and their service providers (Skinner et al., 2009; Joseph et al., 2013). Most recently, in an allied development, scholars have attempted to articulate more thoroughly the importance of place to professional healthcare practices. Indeed, with respect to gerontological nursing for example, studies have attempted to identify the spatial aspects of practice that have the potential to affect the illness and recovery experiences of older people and their health outcomes (Andrews et al., 2005). Meanwhile, other studies have attempted to connect geographical concepts and ideas to some of the more progressive concepts and ideas that drive medicine and healthcare such as client-centeredness, intentionality, autonomy, and quality of care. Here, for example, a geographical perspective has helped to rethink practices associated with the physical and chemical restraint of older people with dementia. Collectively, this emerging research makes a reasonably direct contribution to conversations on evidence-based healthcare.

Emerging Critical Themes

An increasing proportion of the geography of aging, whether it be conceptually focused on space, place, or both, is 'critical' in its orientation. This critical orientation aligns very much to the recent critical/cultural traditions in the two parent disciplines of human geography and social gerontology, and involves

a number of core principles and approaches. The first of these is to challenge social and institutional norms and power relationships. Indeed, the idea is that researchers should not simply accept that the ideas, policies, and initiatives of institutions are appropriate simply because they are provided by those with power and authority. One should question them to expose unequal power relationships and their consequences. The second is to question and interpret dominant models of thinking; the concepts and ideas that underpin policy and practice. Each will have relative merits, success or failures, and specific consequences. The third is to give voice to subjects and issues that are neglected or marginalized in mainstream health and social care practice. Certain people, conditions, and situations – often involving the most vulnerable people and groups – 'fall off the map,' and it is up to researchers to expose and challenge neglect, vulnerability, inequality, and oppression. The fourth is to use qualitative or mixed methodologies to gain detailed and in-depth insights. Human circumstances surrounding lives and care are inherently complex and a range of qualitative research methodologies and associated theoretical and analytical approaches are well suited to investigate, interpret, and convey these. The fifth is to draw on philosophy and social theory to theoretically inform and enhance research. This helps to make sense of empirical observations and articulate some of the underlying meanings and processes involved (see Harper and Laws, 1995). The sixth is to involve communities as partners in research, sometimes taking an activist or advocacy or 'public' approach. Scholars arguably need not neglect this important aspect of their work and might work with various 'publics' to directly encourage reform and change (Andrews and Muzumdar, 2010).

One can observe development and progress in critical research, particularly in a number of theoretical and empirical areas which might be further developed in future. The first of these areas is emotion. Studies in this vein have illustrated not only how public, domestic, and social spaces act to facilitate or constrain the expression of a range of emotions in later life, but also the importance of older people's emotional attachment to place, and the often negative impact of transitions *between* places (Milligan, 2005). The second area is the body. Moving away from treating older people as 'objects' of study, several studies engage with aging and the concept of embodiment, to explore their perceptions of health and aging and their negotiations and changing relationships with spaces and places (Mowl et al., 2005). Specifically studies have reflected on body image and ageist discourses and cultural constructions of aging. The third area is image and stereotypes. Notably, here, research has sought to challenge stereotypes that connect older people solely to 'sick' and 'sad' places (see McHugh, 2003) and examine how and why certain places are, instead, associated with independence, resilience, and well-being in older age. These include, for example, 'unremarkable' places routinely passed through in daily life and specialist places associated with active lifestyles and emerging consumer cultures in aging (Laws, 1995; Mansvelt, 1997; McHugh and Larson-Keagy, 2005). An associated strand of recent research has begun to deconstruct the 'imagined landscapes' of aging identity. In these studies, geographical metaphors are explored, including life's late journeys, paths traveled, autumn years, and the sunsets of lives. The fourth related area is positivity. Commentators have also considered the more positive places and activities of healthy aging – the new landscapes of later life. Examples here include retirement communities, RVing, and Universities of the Third Age. Indeed studies have identified the commodification of healthy aging and as part of this, the radical fracturing of traditional spaces of aging and the common understanding of them. In addition scholars have tended to engage positive aging through a policy critique of issues, such as pensions, lifelong learning, education, physical and social activity, and active citizenship (see Minkler and Holstein, 2008). The fifth and final area is community development. Uncovering the complex, interdependent, and place-embedded local dynamics of older people's experiences of aging and the development trajectories of their communities is seen as crucial for understanding how societies are coping with, and responding to the challenges and opportunities of population aging. Within this theme, the importance of voluntarism is noted as a process through which older people are actively being supported and are actively participating/leading community responses (Joseph and Skinner, 2012; Skinner et al., 2013).

Emerging Critical Theory

While, as suggested, the adoption of critical social theory has emerged in the geography of aging under a post-structuralist paradigm – including engagements with thinkers such as Foucault, Goffman, Deluze, and others – arguably the next step is to come up to speed in other ways with the parent discipline of human geography in understanding and approaching space and place. With this in mind, Andrews et al. (2013) flag relational geography and nonrepresentational theory as two areas worthy of further consideration. Associated with the adoption of post-structuralist theories and perspectives in twenty-first-century human geography has been a 'relational turn.' Basically put, thinking space and place 'relationally' involves rather than envisioning a space as a discrete, bounded area (such as a mapable administrative unit) and a place as a fixed center of meaning (such as a lone house, town, neighborhood, or city), an image of spaces and places as produced through their connections with other spaces and places (Andrews et al., 2013). These ideas have potentially far-reaching implications for the geography of aging. Although the field has long been orientated around the relationship between geographical scales (such as individual, population health, and welfare), new relational ways of thinking potentially extend, and more explicitly theorize, inter-scale relationships in later life. Moreover, the new spatial imaginary of relationality potentially challenges the way scholars approach the fundamental question in the geography of aging: of how and why 'space and place matter to older people'? Namely, it complicates the conventional assumption that there exist 'intrinsic' qualities of spaces (for example, with regard to distance and proximity) and single places (for example, with regard to facets/content and meaning) that affect them (Andrews et al., 2013).

The paradigm of nonrepresentational theory, on the other hand, acknowledges that a sizable portion of the world – what happens 'out there' in everyday life – has been drained from,

and remains unrepresented by much conventional qualitative geographical research, due to traditional philosophical commitments involving theoretically driven interpretative searches for meaning and significance. In contrast, nonrepresentational understandings do not posit an external, material world waiting to be represented and explained away by a researcher. The idea, instead, is that they obtain an understanding of the lived world by engaging with it and understanding it as a performative achievement. Thus, nonrepresentational theory moves the focus of research onto the many subtle and unspoken performances and practices involved in the production and reproduction of life. As Thrift (2007) explains, it conveys the geography of what 'takes place' – the 'bare bones' of occasions and the flow of life. Moreover, because nonrepresentational theory does not seek to explain the human subject, it is, instead, interested in the human body's coevolution with things and relatedness to the world (Thrift, 2007). This involves an attention to the expressiveness, responsiveness, and rhythms of human practice (including performativity, embodiment, senses, and expressions) (Cadman, 2009). As the above explanation indicates, nonrepresentational theory is not really a single theory in itself; rather it is a general way of understanding the active world and undertaking research on it. It is the next stage for scholars to work out what this new paradigm of scholarship means for the geography of aging, and how it fits within, and contributes to the wider discipline of social gerontology (Andrews et al., 2013).

Aging and the Labor Market

Alan Barrett, Economic and Social Research Institute, Dublin, Ireland

Abstract

Population aging will impact on the labor market in at least two ways. First, the number of people in the standard working ages (20–64) will fall. This is generally accepted as being a cause for concern because, all else equal, a smaller pool of workers will have to support a larger number of dependents. Second, the proportion of older workers will rise. This is often thought to be a concern based on the assumption that older people are less productive. The evidence for this turns out to be weak. The relative importance of the two effects suggests that policy should focus on extending work lives.

Introduction

The phenomenon of population aging has been identified as one of the great challenges facing the modern world. The joint occurrence of reduced mortality and lower fertility was initially a feature of the developed world, but increasingly there is evidence that this demographic transition is occurring in less developed countries also. The result is that the age structure of many populations is changing, with an increase in the size of the older population relative to those of younger ages.

Before discussing aspects of the challenges associated with population aging, it is important to say that reduced mortality and hence increased longevity are among the great achievements of humanity. The improvements in mortality in the very recent past (relative to the vast span of human history) have been extraordinary and are now leading us to question concepts such as retirement ages and the nature of retirement itself. While accepting these positives, we also have to accept that the large changes in the age structure of the population do present challenges and will continue to do so as the process unfolds in many countries. The challenges which come to mind most readily and which have received the most attention relate to the costs associated with older age groups and the increase in the ratio of older people to those of working age (the old-age dependency ratio). The costs typically in question are pensions, healthcare, and long-term care. With a relatively smaller number of people of working age, the tax and contribution base falls relative to the increased need. All else equal, these processes combine to put upward pressure on tax or contribution rates and/or downward pressure on benefit and care levels.

It is frequently argued that one of the possible routes through which the challenges of population aging can be solved, or at least eased, is though higher rates of employment including higher rates of participation among older age groups. It is also argued that productivity increases can contribute to meeting the aging challenge, with productivity increases among older workers again forming part of the overall strategy. Such productivity increases could come about through an increase in the capital/labor ratio but also through increases in human capital.

Given the link between the labor market and some proposed solutions to the challenges presented by population aging, it is important to understand how population aging and labor market processes interact. In this article, I will discuss these interactions by drawing on the economic literature on various aspects of the topic. I will begin by presenting some projections on the size of the workforce in a range of countries in the coming years, in terms of the number of people in the standard working age group, 20–64. Benchmark projections are typically based on existing patterns of participation and so can lead to stark findings on likely trends. In particular, labor forces in many countries are projected to shrink. This in itself is not a problem if the numbers outside of the labor force were also falling. However, with the changing population structure and an increasing proportion of older people, the old-age dependency ratio worsens and it is this which gives rise to problems of affordability and sustainability for public services, including pensions.

The labor force projections can then be used to assess what increases in participation would be needed to maintain the labor force at certain levels. In this way, we are provided with a sense of the challenge which policies aimed at increasing participation must address. In this context, the next issue that I will consider is retirement and the factors which determine it. If labor force participation rates among older people are to be increased, it would be desirable in the first instance to reduce early exits from the labor force. To the extent that 65 represents some notion of the 'normal' or 'standard' retirement age, reducing early exits translates into keeping people in the labor force until that age. However, the labor force projections suggest that more will be needed and so extending worker lives beyond 65 would be desirable too. In this situation, the need arises to encourage but also to facilitate active working by people as they move in to the late sixties and beyond. Considerations which arise in this context include the need for flexibility such as part-time work or the option of reduced levels of responsibility.

I noted earlier that in addition to increasing the size of the labor force, it would also be desirable to increase productivity, including that of older workers. For this reason, I will discuss what the literature says on productivity in the later working years. It is worth noting at this point that there often seems to be an assumption within economics and in other subjects that productivity falls as people age and that this inevitably means that productivity will fall in an aging population. As will be seen, the evidence does not support this view and so thought can be devoted to increasing the

productivity of older workers as opposed to merely ensuring that it does not fall too far. The issues which arise here include life-long learning and efforts to avoid skill obsolescence and also the re-organization of work to facilitate older workers. In discussing this area, one issue that arises is the possibility that employers and employees will react to the aging of the workforce without any prompting from government through policy levers. For example, if employers see that the pool of potential employees is aging, they may engage in proactive efforts to make their workplaces more attractive to older workers.

The factors which will lead people to remain in work beyond the normal retirement age and the factors which will increase their productivity are not mutually exclusive. For this reason, the discussion across the topics in the sections later will be interconnected. In the concluding section, I will bring the lessons together and discuss the policy implications. Referring back to the paragraph earlier, the importance of putting in place policies which will make a positive contribution to meeting the challenges posed by aging cannot be understated. In the absence of success in extending working lives and increasing productivity, including among older workers, the challenges posed by population aging will be more difficult to address and so the full benefits of increased longevity will not be realized.

Labor Force Projections

European Commission (2012) provides detailed forecasts of the populations and labor forces of all EU members out to 2060 as part of a larger exercise to examine the implications of population aging for the public finances. Here, I will focus on just two outputs from that report because they capture neatly the issues under discussion. (Projections of this sort are highly uncertain as they require assumptions on a range of trends such as mortality, fertility, and labor force participation rates. Assumptions for migration flows are also needed and these can be the most difficult of all.)

In **Table 1**, I re-produce one of the tables from the European Commission (2012). In this table, the numbers of people aged 20–64 in employment in 2010 are listed for all countries. Based on the projections of population and on assumptions for variables such as rates of participation and unemployment, it is possible to generate projections for employment for all countries out to 2060, for this specific age group. Total employment is, and will be, higher because people under the age of 20 and over the age of 64 also work. However, by focusing in on the 20–64 year olds, we can get a neater picture of what will happen to the size of the group of standard working age. In addition to the value for 2010, the table also shows when the employment of those aged 20–64 will reach its peak and its trough.

Table 1 Projected peaks and troughs in the numbers employed aged 20–64

	Employment 20–64 (in millions)						
	2010 value	*Peak value*	*Year*	*% Change 2010 peak*	*Trough value*	*Year*	*% Change peak trough*
BE	4.4	4.9	2060	11.7	4.4	2010	−10.5

NO	2.3	2.7	2060	18.2	2.3	2010	−15.4
EU27	210.9	217.6	2022	3.2	195.6	2060	−10.1
EA	138.1	143.9	2024	4.2	129.8	2060	−9.8

If we look toward the end of the table at the row EU27, we can get an overall sense of the impact of population aging on the numbers in employment of those aged 20–64. In 2010, just under 211 million of this group were employed across the EU. According to the projections, this number will increase to 217.6 million in 2022 but this is the peak level. This number is then projected to fall continuously through to 2060 when it will reach 195.6 million. This will amount to a peak-to-trough fall of 10.1%. All else equal, this would imply a significant fall in potential output. Hence, the need for increases in employment from other sources, such as through delayed retirement, is clear.

Looking at the countries within the table, there are a number of interesting points to observe. Germany is among the countries with the largest projected declines. Employment levels for the standard working age group were projected to peak in 2012 at 37.2 million. This level was projected to fall to 26 million in 2060, a fall of 31.3%. The country with the largest projected peak-to-trough decline is Romania (−40.9%). Some countries, such as France and the UK, see employment levels among the 20–64 year olds as being at their lowest in 2010 and so the situation facing them appears to be less stark, at least based on the assumptions used in the projections. In the case of the UK, they expect the population aged 20–64 to peak in 2060. In the case of France, the population aged 20–64 is projected to reach its trough in 2038, and not 2060, thereby providing scope for employment increases among this group between 2038 and 2060. In spite of the projections from the UK, France, and some other countries, the broad pattern to emerge from Table 1 is of a shrinking level of employment among those aged 20–64.

In Table 2, I present a different view of the impact of aging on the labor market, again drawing on European Commission (2012). The table shows the employment of those aged 55–64 as a share of total employment among those aged 15–64 in 2010 and projected values for 2060. Looking toward the lower part of the table, it can be seen that for the EU27 in 2010, 13.2% of employment among those aged 15–64 was made up of people aged 55–64. In 2060, this proportion is projected to rise to 18.8%, an increase of 5.5% points. Italy is projected to experience the largest increase in this share – from 12% in 2010 to 23.7% in 2060.

Table 2 Share of older (55–64) employees in total employment, 2010 and 2060 (projected)

Retirement and Extending Working Lives

The decreasing number of those aged 20–64 suggests that participation among those aged 65 and above will have to increase if the numbers employed is to be maintained. In order for this to happen, we need to have a good understanding of why people retire. In this section, I discuss what the literature on this point has said.

Before getting into the literature, it is useful to consider the trend in retirement ages in recent decades. In Table 3, I show data from the OECD on the average effective age at which older male workers withdraw from the labor force – labeled the effective age of retirement. Looking first at the data on the US, it can be seen that in 1970, the age was 68.5 years. By the turn of the century, the age had fallen to 64.7. This was a large change over a 30-year period and was certainly a cause for concern in the context of population aging. However, the effective age of retirement has moved up again in the first decade of this century and was 65.5 in 2010.

Turning to the European Union, the effective age of retirement was 68.4 years in 1970 and so essentially the same as in the US. By 2000, this had fallen to 61.5 years and so the fall over the 30-year period 1970 to 2000 was stronger in the EU countries compared to the US. Like the US, the EU saw an increase in the effective age of retirement between 2000 and 2010 – from 61.5 to 62.5 years. While both the US and the EU experienced an increase in the effective age of retirement between 2000 and 2010, the gap between the two in 2010 is striking – 65.5 in the US and 62.5 in the EU.

Japan provides another interesting comparison. Its effective retirement age was substantially higher than those of both the

Table 3 Average effective age of retirement: men

	1970	*1980*	*1990*	*2000*	*2010*
France	67.6	63.5	60.0	58.8	59.4
United Kingdom	67.7	66.0	62.8	62.4	64.1
Japan	72.3	70.7	70.4	70.1	70.1
United States	68.5	66.4	64.7	64.7	65.5
EU27	68.4	65.1	63.1	61.5	62.5

EU and the US in 1970 (72.3 years). While it has fallen since then, at 70.1 years in 2010, it remained well above the US and EU values.

A number of broader points can be distilled from **Table 3**. First, in many countries the effective retirement age is below the 'normal' retirement of 65. Second, there is diversity across countries in retirement ages. In France in 2010, the age was below 60; as we have seen, in Japan in that year, it was over 70. These observations suggest that there is a range of factors which determine retirement ages, covering financial incentives and health and cultural norms.

Looking first at financial incentives, some of the most influential work can be found in Gruber and Wise (1999, 2004). Focusing on the 1999 volume, the goal of that study was to analyze the incentives for retirement that were generated by the social security systems in 11 countries and to link these incentives to observed retirement patterns. In order to have a common analytical device across all 11 countries, the following approach was adopted. For each country 'social security wealth' (SSW) was calculated which is the present discounted value of the future stream of social security benefits from when the person retires to when they die. By calculating SSW at different ages of retirement, it is possible to see what incentives are generated by the social security system.

To see how a system can generate incentives toward early retirement, consider the following example which is not atypical of the systems examined in Gruber and Wise (1999). Suppose a social security system allows people to draw benefits at age 62 and suppose that there is no increase in benefits if the person chooses to retire later than 62. In this case, SSW will be lower at age 63 compared to age 62 because the person will draw benefits for 1 year less (assuming that the timing of death is not affected by the timing of retirement). The fall in SSW can be viewed as a tax on working longer. If the person works beyond 62, (s)he will have earned income but if the SSW-related tax is sufficiently large, there will be a clear incentive to retire at 62. Even if the social security benefits are increased between 62 and 63, there will be an incentive for early retirement if the adjustment to the benefits is not actuarially fair.

The country-specific chapters in Gruber and Wise (1999) uncover evidence of incentives toward early retirement inherent in the design of many social security systems. In the case of some countries, the issues relate to payments other than old-age pensions; unemployment and illness/disability payments also have eligibility conditions which facilitate early retirement. Generally, the studies find patterns of retirement that are consistent with the incentives, notably, that a retirement spike occurs when benefits first become available. They also show that a second spike typically occurs around 65, the normal retirement age. This second spike cannot be readily explained in terms of financial incentives and suggests that cultural norms play a role in determining retirement choice. Generally, one of the striking outcomes from the Gruber and Wise study is the similar reactions to financial incentives across countries.

As noted with respect to **Table 3**, effective retirement ages had been falling in many countries up to 2000. Combined with fears over the sustainability of their systems (and possibly recognizing the design flaws as highlighted by Gruber and Wise, 1999), many governments implemented reforms in the last two decades (for a fuller discussion see Martin and Whitehouse, 2008). It is tempting to conclude that these reforms have been successful based on the increases in the effective retirement ages observed since 2000. Coppola and Wilke (2010) suggest that reforms in Germany have been successful in terms of raising the expected ages of retirement. Barrett and Mosca (2013) suggest that reforms in Ireland were less successful in achieving that goal, at least in the immediate aftermath of the announcement of the reform.

While financial incentives clearly play a role in retirement decisions, it seems likely that health would also play a role. Prior to the widespread availability of panel data, generating evidence on this point was difficult. As discussed in Bazzoli (1985), papers based on cross-sectional data which showed a strong positive link between health status and retirement may have suffered from 'ex post rationalization' on the part of survey respondents. By this, she meant that poor health could be used by respondents to explain the fact that they were currently retired, even if poor health had not prompted the retirement.

With the arrival of longitudinal datasets, such problems are reduced (although not necessarily eliminated). Emmerson and Tetlow (2006) use the first two waves of the English Longitudinal Study on Aging (ELSA) (2002/3 and 2004/5) to explore the differences in health status across people who exited the labor market and those who remained in it. Looking at people aged between 50 and 65, they show that people who reported that their health was either poor or fair were about twice as likely to exit the labor force compared to people who reported that their health was very good or excellent. This tendency toward exit for those in poor health was more prominent for those employed in manual occupations. Almost a third of male manual workers who reported fair health or worse at the first wave had left the labor force by the second wave; the corresponding figure for non-manual workers was just under a fifth.

McGarry (2004) looks at the link between health and retirement in a different way. She poses the question of whether or not retirement expectations are affected by health. The data which she uses, the US Health and Retirement Survey (HRS), include information arising from the following question:

> Thinking about work generally and not just your present job, what do you think are the chances that you will be working full-time after you reach age 62?

Using responses to this question as the explanatory variable, she relates health to retirement expectations, along with other variables including those related to finances. She finds that health does affect retirement expectations and also that the size of the effect is larger than that of the financial variables. She also finds that *changes* in health status give rise to *changes* in retirement expectations.

Before leaving this discussion of the impact of health on retirement, it is worth noting that researchers, including economists, have also explored whether retirement has an impact on health. One recent example is Behncke (2012) and her results are striking. Using the first three waves of the English Longitudinal Study on Aging, she finds that retirement

increases the risk of severe cardiovascular disease and cancer. Retirement also appears to increase risk factors for such conditions including BMI, cholesterol, and blood pressure. More generally, retirement seems to reduce self-assessed health. These findings lead Behncke to conclude that delaying the age at which the state pension is paid could be a policy tool for improving public health.

Productivity

Economists have long been interested in the relationship between age and productivity, but this interest was often motivated by an interest in the relationship between age, pay, and productivity together. Specifically, economists have theorized that the gap between productivity and pay is negatively related to age, and this seems to be related in part to an assumption that productivity declines with age whereas wages are assumed not to fall. If this is true, it has implications for the employability of older workers. Another possible implication is the need for mandatory retirement, as explained by Lazear (1979). In his model, younger workers are paid less than their marginal product at the early stages of their careers but they are 'promised' pay increases if they remain with the firm. This leads to higher degrees of attachment to the firm and the resulting lower rates of employee turnover allows for greater productivity. However, beyond a certain age, pay exceeds marginal product and this gives rise to the need for mandatory retirement.

Van Ours (2009) is among a group who have tried to look for direct evidence that productivity declines with age. He begins with a rather limited perspective and uses data on runners to assess whether physical capacity declines with age. He then uses data on the publication rates of academic economists to see if cognitive capacity diminishes. He finds evidence of declines with respect to his measure of physical capacity but not with respect to cognition.

He expands the scope of the analysis by using a linked employer–employee data set from the Netherlands to see whether the pay–productivity gap is related to age. He does not find evidence of a relationship. While his results are interesting, his conclusion is perhaps more striking. He says that the potential negative impacts of population aging on productivity should not be underestimated, but he also cautions that they should not be overestimated either.

Estimating the link between productivity and age at the level of the firm is a complicated task. Studies typically look at the share of employees of different ages and relate this to productivity levels across firms with different age structures. This basic formulation gives rise to many complicated methodological issues. For example, older employees may work in longer-established firms where the capital stock is older. In this case, a naive view of the age–productivity relationship would show older workers to be less productive but this would not be true. It could also be the case that outputs and labor input are determined simultaneously by firms and so a host of endogeneity issues arise.

Some studies have attempted to grapple with these issues. Aubert et al. (2006) explore the issue of the pay–productivity and age relationship, using a linked employer–employee dataset from France which includes information on 70 000 firms over the period 1994–2000. They find that productivity increases up until the age of 40 and then remains stable. This pattern is found to hold in each of the three sectors covered: manufacturing, trading, and services. They also find that the age–productivity profile is similar to the age–wage profile, and so their evidence does not support the notion of a divergence between productivity and wages at later ages.

Göbel and Zwick (2009) use German linked employer–employee panel data and they focus on estimating the relationship between age and productivity. They find that productivity at the firm level increases with the age of the employees up to the age of 55. Thereafter, there is only a slight decrease. Although they find little evidence of productivity falls on average, they also point out that there are large variations across firms in their sample. This implies that productivity falls with age in some settings, which in turn could be related to the nature of the work being undertaken. Göbel and Zwick also suggest that the maintenance of productivity levels in some firms may be related to the personnel policies operated by different firms.

Göbel and Zwick (2013) explore whether or not workplace policies aimed specifically at older workers can help to maintain the productivity levels of those older workers. They use a rich German dataset which includes information on the age structure of the employees of a large sample of firms and also output measures. The survey also includes questions on whether specific human resource measures for older workers were implemented. Although seven such measures were listed in the relevant question, Göbel and Zwick collapse them into the following five categories: specific equipment in workplaces; reduced working hours for old employees; age-specific jobs for old employees; mixed-age working teams; and training for old employees.

A mixed pattern of results emerged. Productivity levels among older workers were found to benefit from specific equipment in the workplace and from age-specific teams. Training for older workers and reduced working time were not found to have an impact. Possibly the most interesting result was with respect to mixed-age teams. In this case, the productivity of both older and younger workers was increased. Göbel and Zwick explain this result through the positive spillovers that arise when different skill sets and perspectives are brought to bear on an issue. This line of thinking has a parallel in the literature on immigration, where it is increasingly argued that the diversity in the workplace which results from immigration can also yield positive spillovers (Ottaviano and Peri, 2006). This is an important result because it recognizes the potential complementarities between younger and older workers and the scope this provides for productivity increases.

A different perspective on the age–productivity relationship is explored by Aubert et al. (2006) and Behaghel et al. (2014). The issue in these papers is whether technological change and innovative workplace practices reduce the demand for older workers, which can be taken to imply a fall in productivity relative to younger workers. Aubert et al. (2006) point out two routes through which effects could operate. First, to the extent that technological change leads to skills obsolescence, this is more likely to affect older workers who acquired their

skills in the past. The impact of technological change on lower skilled workers has been discussed extensively in the economics literature and has been proposed as an explanation for increasing income inequality (Levy and Murnane, 1992). Given this, it is unsurprising that the impact of technological change on older workers would have become a source of interest and concern. The second route through which innovation in the workplace could affect older workers is through less adaptability on their part. If new forms or work organization or new production processes require significant level of adaptation, this could be more challenging for workers who have operated in a particular setting for longer.

Based on a dataset of French firms, Aubert et al. (2006) found that the wage bill of older workers fell in the more innovative firms and that it rose for younger workers. This suggests that the demand for older workers fell relative to younger workers in these settings. The precise mechanism underlying the observation differed depending on whether the innovation related to technology or organizational change. In the case of technological introductions, the hiring of older workers fell. In the case of organizational innovation, rates of exit among the young fell.

Behaghel et al. (2014) expand this analysis. Using the same data set, they explore whether the negative effects on the share of older workers that resulted from innovation at the firm level can be offset by training. Their results show that while training for older workers can mitigate the effects shown by Aubert et al. (2006), such training does not offset the effect completely.

On balance, the evidence would seem to suggest that some of the assumed impacts on productivity of population are overstated. However, specific issues such as technological change do, and will, present specific challenges.

Conclusion

In this article, I have identified two routes through which population aging will impact the labor market. As the labor force is drawn primarily from those aged 20–64, the decrease in the number of this age group in many countries will lead to a fall in the labor force, all else equal. As this reduced labor force would have to support a larger number of older people, again all else equal, this is clearly a potential problem. In addition to the projected fall in labor forces, population aging will also result in an increase in the share of older workers. While many assume that this will lead to lower levels of productivity, based on the notion that older people are less productive, the evidence presented earlier suggests that any decreases in productivity will probably be limited (see Börsch-Supan, 2003, for further evidence on this).

This line of reasoning leads to the conclusion that the dominant policy concern in the aging/labor market intersection is with maintaining the size of the labor force and the old-age dependency ratio through delaying retirement. The first step on this road should be the elimination of financial incentives for early retirement, whether in the pensions system or in other elements of the welfare system such as unemployment or disability payments (Gruber and Wise, 1999). The second step should be the development of the working environment so that it facilitates and encourages delayed retirement (Göbel and Zwick, 2013). It could be that firms will choose to develop their workplaces in an 'age-friendly' response to the changing age structure of the population. Nevertheless, policy makers should still monitor this aspect of the workplace and consider active policy measures if progress is slow.

Better health is a contributing factor to population aging and also to delayed retirement. For this reason, we may witness (and may already be witnessing) a process whereby population aging sees a parallel extension in working lives. This is one of the potential processes that allow us to be less concerned about the potential impacts of population aging.

As a final note, the observation that retirement can be bad for your health is a potentially powerful message. As retirement is a decision which is difficult to reverse, there is less scope to 'experiment' than would be the case with other life choices. This means that people may be unaware of the fact that retirement is not necessarily 'bliss' (to quote Börsch-Supan, 2013) and so may be encouraged to remain in work if the possible impacts of retirement were more fully understood.

Aging and Work

Abstract

Even though we tend to think of and study age as one's age in calendar years, other conceptualizations of age exist, such as how long one has been in their current job or organization. Empirical research suggests that the way age is defined can impact the way it impacts a variety of outcomes in the workplace, such as absenteeism, innovative behavior, and safety behavior. In addition, empirical research suggests the negative stereotypes that are held about older workers typically are not supported with data. In fact, data often suggest the relationships are very different than the negative stereotype suggests.

The empirical study of aging in the workplace is increasing in importance, as changes in demographic trends (e.g., decline in birth rates and increasing life expectancy) have caused economic challenges (e.g., employees need to work longer to support the changing infrastructure of retirement systems), technical challenges (e.g., training older workers for changing technologies), and require greater cultural awareness and sensitivity due to increased globalization (Truxillo and Fraccaroli, 2013). The purpose of this article is to review how aging and its numerous different conceptualizations impact performance and functioning in the workplace. Although this article will almost entirely examine age effects on workplace outcomes as developmental, it is important to briefly describe two other types of aging effects.

Age-Related Effects

One difficulty in studying aging in the workplace is distinguishing between three types of aging effects, including developmental, cohort, and period (Parry and Urwin, 2011). In the context of the workplace, developmental effects refer to how workplace outcomes change as individuals' age or mature, whereas cohort effects refer to how historical events shape the workplace for differently aged employees. Generational cohorts have been defined as "an identifiable group that shares birth years, age location, and significant life evens at critical development stages" (Kupperschmidt, 2000: p. 66). Although the major cohorts have been operationally defined using many different year ranges, the most common conceptualization is that the Baby Boomer generation includes those born between 1946 and 1964, Generation X includes those born between 1965 and 1980, and Generation Y includes those born between 1981 and 1999 (Meriac et al., 2010). Finally, period effects refer to how the environment and values of the environment shape the workplace (Parry and Urwin, 2011). This article focuses almost exclusively on aging as developmental effects, though we recognize that cohort effects and period effects may also impact important workplace outcomes. Focusing on developmental effects, there are several different conceptualizations of age that can impact the relationship between age and workplace outcomes.

Different Conceptualizations of Age

Even though the majority of empirical research and popular press articles conceptualize age as chronological age, or one's age in calendar years, several other conceptualizations of age exist, including *functional/performance-based age*, *psychosocial/subjective age*, *organizational age*, and the *life span concept of age* (Kooij et al., 2008; Sterns and Doverspike, 1989). Functional age refers to one's age in terms of performance, regarding aspects such as cognitive ability and health.

Psychosocial age refers to how old one feels, thinks, acts, or desires to be. Organizational age captures one's age from an organizational perspective in terms of concepts like job tenure (length of time in one's current role), organizational tenure (length of time at one's employing firm), and career stage. Job tenure refers to the length of time one has been in their current functional role or job, whereas organizational tenure refers to the length of time one has been in their current organization. Finally, the life span concept of age refers to how aging processes might differ across one's life span, taking into consideration changes across life stages such as caring for young children or aging parents (Kooij et al., 2008). Even though there is substantial overlap between the different conceptualizations of age (e.g., between chronological age and organizational tenure), this article will illustrate how often, the *magnitude* of age predicting workplace outcomes depends upon the definition of age one uses.

Because more research has examined how chronological age, job tenure, and organizational tenure impact workplace outcomes relative to other conceptualizations of age, this article will place more focus on the chronological and organizational conceptualizations of age. Given the preponderance of workplace stereotypes about age, we begin each section by describing the stereotype and then discuss the extent to which empirical research supports or refutes the stereotype.

Age and Workplace Outcomes

One of the most common negative stereotypes of older workers is that older workers have lower levels of job performance than younger workers (Ng and Feldman, 2012). Three meta-analyses conducted by Ng and Feldman (2008, 2010b, 2012) have

examined how chronological age, organizational tenure, and job tenure, respectively, impact job performance. Meta-analytic results suggested the strongest age–job performance relationship was between organizational tenure and performance, with organizational tenure positively predicting core task performance (Ng and Feldman, 2010a). Even though organizational tenure positively predicted job performance, it only accounted for slightly over 1% of its variance. Therefore, the practical significance of the relationship is low. In addition, the positive relationship between organizational tenure and core task performance goes against the conventional negative stereotype that younger workers are better performers than older workers (Posthuma and Campion, 2009). On the contrary, these results suggest that the socialization process and experience workers have from working in an organization actually help improve their task performance, although the effect is small. When considering chronological age, however, meta-analytic results suggest there is no relationship between age and job performance (Ng and Feldman, 2008) or job tenure and job performance (Ng and Feldman, 2013a).

One explanation for the weak relationship between different conceptualizations of age and job performance is the presence of moderators. This proposition is supported by meta-analytic results that suggest the organizational tenure – job performance relationship was stronger for younger workers (those under age 37) compared to older workers (those over age 37; Ng and Feldman, 2010a). This finding is in line with the popular term 'Peter Principle,' which states that employees are promoted until they reach their own level of incompetence (Peter and Hull, 1969). To the extent to which it is more likely older workers have reached their level of incompetence relative to younger workers, this finding seems reasonable. Meta-analytic evidence also suggests that the organizational tenure-job performance relationship may be curvilinear in nature. Specifically, meta-analytic evidence suggests the organizational tenure–job performance relationship is significantly stronger at 3–6 years of organizational tenure relative to 0–3 years, 7–10 years, 11–14 years, and greater than 14 years (Ng and Feldman, 2010a).

Even though meta-analytic evidence suggests the age–job performance relationship is rather weak, research suggests the negative *stereotype* that older workers have lower levels of job performance than younger workers can impact behavior in the workplace. For example, research using a laboratory study found that the older target received more severe punishment recommendations than the younger target for making a mistake (Rupp et al., 2006). In addition, this research found that individuals with high levels of agism, or prejudice toward older individuals, gave significantly more severe punishment recommendations to the older target compared to the younger target (Rupp et al., 2006).

Similarly, research on the perceived productivity of workers across the life span revealed that employees under the age of 49 rate the perceived productivity of employees over 50 years old significantly lower than employees over 50 years old (Van Dalen et al., 2010). Perhaps more importantly, the aforementioned finding was found to be even stronger using a subset of the sample who self-identified as owners, heads of human resources departments, managing directors, and plant managers (Van Dalen et al., 2010). This finding suggests the negative stereotype that older workers are less productive than younger workers is strongest at the highest levels of organizations, thereby increasing the likelihood of litigation and increasing the likelihood that a culture of negative stereotypes toward older workers will permeate to the rest of the organization.

Given all the meta-analytic evidence, it seems the negative stereotype that a negative relationship exists between age and job performance is not warranted. That being said, findings suggest the negative stereotype does seem to affect how individuals perceive older workers when they make mistakes, and may impact the selection of qualified older workers for jobs when competing with qualified younger workers. Finally, results suggest years in one's organization are a better predictor than one's chronological age of job performance. To the extent to which one better learns how to navigate corporate policy and the culture of their organization after more time with that organization, this finding is warranted.

Training Performance

The negative stereotype also exists that older workers are less likely to seek out training and development or learning opportunities to grow in their career or position (Posthuma and Campion, 2009). Research regarding this negative stereotype is largely mixed. Specifically, one meta-analysis that examined the relationship between chronological age and training mastery found a moderate negative correlation, signifying that as individuals age, their training mastery decreases (chronological age accounted for 6% of the variance in training mastery; Kubeck et al., 1996). More recently, meta-analytic evidence found no effect of chronological age on performance (Ng and Feldman, 2008) or participation (Ng and Feldman, 2012) in training programs. Even though more evidence is needed to determine whether chronological age dampens training performance or participation, chronological age does seem to impact motivations that occur during the training process. Results of a meta-analysis found a small negative relationship between chronological age and both motivation to learn and learning self-efficacy, with chronological age accounting for 2–3% of the variance in those outcomes.

In summary, research regarding the effects of aging on training performance and related outcomes are rather mixed. Even though there does not seem to be an impact of chronological age on training participation, research does suggest chronological age negatively impacts training performance, motivation to learn, learning and learning self-efficacy. Given these findings, organizations would be wise to carefully select older workers for training sessions, and try to determine ways to increase their motivation to complete the training task.

Career Development

Another negative stereotype is that older workers have lower levels of career development motivation and behavior relative to younger workers (Ng and Feldman, 2012). Similar to motivation to learn and learning self-efficacy, meta-analytic results indicate as individuals' age chronologically, they tend

to have slightly lower career development motivation, as well as engage in slightly fewer career development behaviors (Ng and Feldman, 2012). Interestingly, findings suggest this negative relationship between chronological age and career development behaviors is stronger when the ratings were other-ratings as opposed to self-ratings, with chronological age of the target employee accounting for nearly 5% of the variance in career development behaviors rated by others (Ng and Feldman, 2012).

One possible explanation for the negative relationship between chronological age and career development behavior is that younger employees have greater access to career development within their organization than older employees. Recent research found that employees aged 26 years or younger reported greater opportunities for career development compared to those aged 36–42 years. Similarly, employees with less than 3 years of organizational tenure had greater access to learning and development opportunities compared to those with 3–10 years or greater than 10 years of organizational tenure (Pitt-Catsouphes et al., 2009).

In summary, results suggest a slight decrease in career development motivation and behavior as employees' age, both chronologically and within their organization, although the effect is rather small. Even though the relationship between chronological age and career development behaviors/motivation is rather weak, it can be augmented by the negative stereotype that older workers have much lower career development aspirations compared to younger workers. While the finding that career development behaviors decrease with age has been well supported by previous research, it is rather unclear whether this occurs because organizations focus their career development effort and resources more on younger employees, or whether career development interests decline as individuals age within the organization and chronologically.

Innovation/Resistance to Change

Another negative stereotype states that older workers are more resistant to change and have lower levels of innovation compared to younger workers (Posthuma and Campion, 2009). Recent empirical research found that contrary to this popular negative stereotype, younger workers were more resistant to change than older workers (Kunze et al., 2013). In addition, meta-analytic results found a weak positive relationship between chronological age and innovative behavior (Ng and Feldman, 2013b). Qualifying the main effect, findings suggest the relationship between chronological age and innovative behavior is curvilinear in nature, such that the relationship is stronger at less than 35 years of age compared to those over 35 years of age (Ng and Feldman, 2013b). This finding indicates the impact of age on innovation is greatest before age 35, and that after employees reach that age, there is no impact of age on innovative behavior.

Results are even more striking when examining the relationship between job tenure and innovative behavior. A recent meta-analysis found a rather strong positive relationship between job tenure and innovative behavior, with job tenure accounting for 6–12% of the variance in innovative behavior, depending on whether the ratings were self or supervisor ratings of innovative behavior, respectively (Ng and Feldman, 2013b). Qualifying the main effect, meta-analytic results suggest the relationship between job tenure and innovative behavior is curvilinear in nature, such that the relationship is strong at less than 10 years of job tenure, but no relationship exists at over 10 years of job tenure (Ng and Feldman, 2013b). This finding suggests that it may be easier to innovate with more experience on the job. However, after 10 years at the same job, the link from experience to innovation becomes weaker.

Even though meta-analytic evidence suggests that older workers actually tend to have higher levels of innovation and less resistance to change than younger workers, the negative stereotype that younger workers engage in higher levels of innovative behavior than older workers is real, and has consequence for older workers. For example, one study employing a laboratory design found that younger targets were rated more positively than older targets in regards to a number of dimensions of adaptive performance, including solving problems creatively, learning work tasks, cultural adaptability, interpersonal adaptability, and physical adaptability (DeArmond et al., 2006). In summary, contrary to the popular stereotype, innovative behavior actually increases with chronological age. In addition, job tenure positively predicts innovative behavior until age 35. Organizations would be wise to develop age diverse teams, both in terms of chronological age and job tenure to in order to maximize innovative behavior.

Organizational Citizenship Behavior/ Counterproductive Work Behavior

The positive stereotype also exists that older workers are more dependable, honest, and trustworthy than younger workers (Posthuma and Campion, 2009). One reasonable manifestation of this positive stereotype is the proposition that older workers have higher levels of organizational citizenship behaviors and lower levels of counterproductive work behaviors relative to younger workers. Organizational citizenship behaviors are extra, unexpected behaviors that better one's immediate work group or environment (e.g., helping a coworker), whereas counterproductive work behaviors are behaviors that intentionally harm business (e.g., stealing, using inappropriate language; Ng and Feldman, 2008). Meta-analytic evidence partially supports this positive stereotype. Older workers and those with higher levels of organizational tenure do tend to engage in slightly higher levels of organizational citizenship behavior and lower levels of counterproductive work behavior relative to their younger counterparts, and those with lower levels of organizational tenure, respectively, although the effect is relatively small (Ng and Feldman, 2008, 2010a). It is important to note that a stronger relationship was found between chronological age and organizational citizenship behavior directed at tasks (e.g., displaying extra effort on the job), with chronological age accounting for over 4% of the variance (Ng and Feldman, 2008). Thus, older workers are more willing to persist to try hard to improve personal or group performance relative to younger workers. In addition,

meta-analytic results suggest a positive relationship exists between job tenure and organizational citizenship behaviors, and that no relationship exists between job tenure and counterproductive work behaviors (Ng and Feldman, 2013a).

Moderators of the chronological age- counterproductive work behavior and organizational tenure–organizational citizenship behavior relationship exist. Specifically, recent research found the negative relationship between chronological age and counterproductive work behaviors is strongest for those over age 40 and lowest for those under age 25 (Ng and Feldman, 2008). In addition, meta-analytic results suggest the organizational tenure-organizational citizenship behavior relationship is stronger for younger workers (those under age 37) compared to older workers (those over age 37; Ng and Feldman, 2010a). Meta-analytic evidence also suggests that the organizational tenure–organizational citizenship behavior relationship may be curvilinear in nature. Specifically, meta-analytic evidence suggests the organizational tenure – organizational citizenship behavior relationship is significantly higher at 0–3 years of organizational tenure relative to 3–6 years, 7–10 years, 11–14 years, and greater than 14 years (Ng and Feldman, 2010a).

In summary, there seems to be a small positive relationship between three conceptualizations of age (chronological age, job tenure, and organizational tenure) and organizational citizenship behaviors. Given the organizational tenure–organizational citizenship behavior relationship is stronger at both younger ages and lower levels of job tenure, it is difficult to tell whether it is the organizational tenure or age that is specifically driving the moderation. However, to the extent to which organizational citizenship behaviors may increase one's chances of being promoted or receiving other positive workplace outcomes, it is more likely that years of tenure moderates the relationship between organizational tenure and organizational citizenship behaviors.

Absenteeism

Another positive stereotype of older workers is that older workers have lower levels of absenteeism relative to younger workers (Ng and Feldman, 2012). This stereotype seems to be based on fact since the strongest impact of age on performance outcomes can be found with absenteeism. Supporting the positive stereotype that older workers are more dependable than younger workers (Posthuma and Campion, 2009), meta-analytic results suggest that chronological age has the strongest impact on employee tardiness and absenteeism. Indeed, chronological age accounts for 7% of the variability in tardiness and absenteeism, with younger workers showing greater levels of tardiness and absenteeism than older workers (Ng and Feldman, 2008). A similar, albeit weaker trend, has been found in regards to organizational tenure, such that workers with higher levels of organizational tenure display lower levels of absenteeism (Ng and Feldman, 2010a). Contrary to chronological age and organizational tenure, job tenure has no impact on absenteeism (Ng and Feldman, 2013a). In summary, supporting the positive stereotype toward older workers, chronological age is a robust predictor of employee tardiness and absenteeism.

Safety Behavior

Similar to absenteeism, another positive stereotype of older workers is that older workers have higher levels of safety behavior relative to younger workers (Ng and Feldman, 2012). Safety behavior can generally be defined as the extent to which employees obey safety rules (Ng and Feldman, 2008). One reasonable manifestation of this stereotype is that older workers engage in greater levels of safety behavior or compliance relative to younger workers. Meta-analytic evidence supports this proposition, as findings suggest a negative relationship exists between organizational tenure and safety behavior, with organizational tenure accounting for over 3% of the variance in safety behavior (Ng and Feldman, 2010a). Meta-analytic evidence suggests a positive relationship exists between chronological age and safety compliance, and that older workers have lower incidences of workplace injuries relative to younger workers (Ng and Feldman, 2008), although the effects are lower than those accounted for by organizational tenure. Findings suggest there is no relationship between job tenure and safety compliance (Ng and Feldman, 2013a). In summary, older workers and workers with higher levels of job tenure tend to have slightly higher levels of safety behavior relative to younger workers and less tenured employees, respectively. These findings have important ramifications for organizations, which may be well advised to target their safety training on young employees and newly hired employees.

Age and Workplace Attitudes

In addition to safety behavior, the positive stereotype exists that older workers have higher levels of organizational commitment and lower levels of turnover intentions relative to younger workers (Ng and Feldman, 2012). Unlike many of the other workplace outcomes, much research has examined the existence of possible developmental and cohort effects on workplace attitudes. In regards to cohort effects, a recent meta-analysis examined the relationship between cohort and workplace attitudes including job satisfaction, organizational commitment, and turnover intentions (Costanza et al., 2012). Results suggested that older cohorts (e.g., Baby Boomers and Generation X) tended to have slightly higher levels of job satisfaction and organizational commitment than younger cohorts, although there was a wide level of variability in the findings of primary studies. In regards to turnover intentions, results suggested that Generation Y tends to have higher levels of turnover intentions than Generation X and Baby Boomers (Costanza et al., 2012). However, since the differences between the cohorts on workplace attitudes were rather small, Costanza et al. (2012) concluded that the practical significance of cohort differences in workplace attitudes was rather low.

In regards to developmental effects, a recent meta-analysis examined the relationship between chronological age and three broad types of job attitudes, including task-based attitudes (e.g., job satisfaction), attitudes toward others (e.g., coworker support), and organization-based attitudes (e.g., organizational commitment; Ng and Feldman, 2010b). In regards to task-based attitudes, meta-analytic analyses suggested a small

positive correlation between chronological age and job satisfaction, with chronological age accounting for over 3% of the variance in job satisfaction. On the other hand, analyses found a strong negative correlation between chronological age and satisfaction with promotion, with chronological age accounting for nearly 10% of the variance in satisfaction with promotion. Analyses also revealed small positive correlations between chronological age and job involvement and intrinsic motivation, as well as small negative correlations between chronological age and role overload and role ambiguity (Ng and Feldman, 2010b).

Meta-analytic results also suggested the relationship between attitudes toward others and chronological age was largely nonexistent, although results did suggest a small positive relationship between age and satisfaction with coworkers/supervisors, although chronological age only accounted for 1% of the variance in that outcome. In regards to organization-based attitudes, results suggested a small positive correlation between chronological age and organizational commitment and its facets (e.g., affective commitment, normative commitment), with age accounting for 4–6% of the variability in the facets of organizational commitment (Ng and Feldman, 2010b). It is worth noting that while controlling for job tenure did decrease the strength of the relationship between chronological age and the aforementioned attitudes, the relationships still existed.

In addition to the aforementioned attitudes, research has examined how age impacts retirement intentions and decisions. As one might expect, chronological age positively predicts retirement intentions (van Solinge and Henkens, 2009), although perceived life expectancy is a stronger predictor of retirement intentions than chronological age. Indeed, employees who feel they will live longer tend to have lower retirement intentions (van Solinge and Henkens, 2009). This research also found that the life span concept of age impacted retirement intentions, as employees with partners had lower levels of retirement intentions relative to those without partners. Meta-analytic evidence also suggests the performance-based age conceptualization of age predicts retirement behavior, as poor health is a weak, but significant predictor of making the decision to retire (Topa et al., 2009). The specific health markers that have the greatest impact on retirement attitudes and behavior, as they increase with age, seem to be blood pressure and cholesterol. Age accounts for 10% of the variability in blood pressure and 4% of the variability in cholesterol (Ng and Feldman, 2012).

One organizational intervention that seems to impact both task-based attitudes (e.g., job satisfaction) and retirement intentions is the use of flexible work arrangements (e.g., flextime, compressed work weeks, telecommuting; Baltes et al., 1999). Indeed, research suggests flexibility and having input on one's schedule positively predicts perceptions of supervisor effectiveness, which in turn positively predicts job satisfaction of older workers (James et al., 2007). Research also suggests that flexible work solutions lead to increased volunteering on the part of older workers, which in turn leads to decreased turnover (Havens and McNamara, 2007). As a specific example of an organizational intervention, the CVS Snowbird program allows US employees working for CVS to relocate for seasonal employment to a different CVS location in another area of the country, while keeping their current job (The Sloan Center on Aging & Work, 2012). With this program, CVS has decreased turnover and increased the percentage of older employees part in their workforce (The Sloan Center on Aging & Work, 2012). You can keep update to date on the most recent research around aging a multitude of issues in the workplace such flexible work arrangements by visiting the Web site of the Sloan Center on Aging & Work (http://www.bc.edu/research/agingandwork/).

In summary, results suggest that generally, there are weak relationships between age and workplace attitudes. One notable exception is satisfaction with promotion, as older employees have significantly lower satisfaction with promotion. It is worth noting that developmental effects and cohort effects were very similar across the two meta-analyses. However, in both cases, results suggested the effect of increased job satisfaction for older workers or Baby Boomers was rather weak. In addition, older employees, and especially those employees without partners or with health problems are likely to have higher turnover intentions than their counterparts. One type of organizational intervention that can successfully decrease retirement and/or turnover intentions and increase job satisfaction for older employees is the use of flexible work schedules. Given the success of flexible work schedules to increases employee satisfaction, more organizations would be wise to consider this organizational intervention when possible.

Workplace Motives

Another negative stereotype of older workers is that they place more importance on work relative to family (work–family conflict) than younger workers (Ng and Feldman, 2008). Recent research found the relationship between work–family conflict and age may be curvilinear in nature, as work–family conflict was lowest for younger and older workers, and highest for workers in the middle age group (Huffman et al., 2013). One explanation for this finding is that the life span conceptualization of age may be more important for predicting work–family conflict than chronological age. Indeed, a review of the work–family conflict literature found that generally, work–family conflict decreases as individuals move from having preschool children to have adolescent children (Baltes and Young, 2007). Given the curvilinear nature of the chronological age – work–family conflict relationship, it is not surprising that a meta-analysis found no relationship between chronological age and work–family conflict (Ng and Feldman, 2012).

In addition to importance of work relative to family, much previous research has examined how motives for working change as individuals move across the life span. Specifically, Kooij et al. (2011) found no effect of chronological age on social motives (motives that include interacting with others as a focal point). Results suggested a small positive correlation between chronological age and intrinsic motives for working, although the effect was rather small (accounted for less than 1% of the variability in the outcomes). Results suggested small negative correlations between chronological age and

growth motives, as well as security motives and extrinsic motives for work, although the effect was rather small (accounted for less than 1% of the variability in the outcomes). Meta-analytic results also found a moderate positive correlation between chronological age and autonomy needs and a moderate negative correlation between chronological age and need for promotion (chronological age accounted for between 5 and 7% of the variance in the outcome; Kooij et al., 2011). Further moderator results suggested the relationship between age and several workplace motives may actual be curvilinear in nature. For example, results suggested the relationship between chronological age and social motives was negative for younger workers, positive for middle-aged workers, but not significant for older workers (Kooij et al., 2011).

In summary, chronological age impacts several motives for working, including autonomy and promotion needs. In addition, the life span concept of age factors such as age of youngest child and marital status are meaningful predictors of the importance one places on work relative to family (e.g., work–family conflict). These findings have important implications for ways that organizations motivate employees across the life span. For example, older employers are less likely to be motivated by promotions and more likely to be motivated by being given a choice on how and/or where to perform their work. In addition, organizational interventions such as flexible work arrangements may be best utilized for those employees with young children in order to minimize work–family conflict.

Conclusions

In conclusion, age (and the way it is defined) impacts a variety of work outcomes that matter to individuals (e.g., job satisfaction), organizations (e.g., job performance), and societal structures (e.g., importance of work relative to family). As seen in Table 1, chronological age seems to have the greatest impact on health, absenteeism, career development behaviors rated by others, need for autonomy, and organizational commitment. As seen in Table 2, organizational tenure seems to have the greatest impact on innovation. As seen in Table 3, job tenure has the greatest impact on absenteeism and safety behavior.

Even though by definition, there is a large amount of overlap between these three definitions of age, the magnitude of their relationships with important workplace outcomes differ to a greater extent than seems to be typically recognized in the literature. It also seems that several conceptualizations of age are notably understudied in the applied literature, including performance-based age and psychosocial age. Given that the magnitude of the relationship between age and workplace outcomes depends on how you define age, it would be worthwhile to examine these underutilized definitions of age are related to important workplace outcomes. Finally, future research should also place increased attention to the life span concept of age and use more complicated designs (e.g., longitudinal). The many curvilinear relationships shown throughout Tables 1–3 suggest life span concept of age variables such as marital status and youngest age of child play an important role in predicting workplace outcomes.

Table 1 Effects of chronological age on workplace outcomes

Outcome	*Finding*	*Magnitude*
Job performance	● No relationship	● None
Training performance	● Mixed for training performance	● None
	● (−) For motivation to learn and learning self-efficacy	● Small
Career development	● (−) For career motivation and behaviors	● Small
	● (−) For career behaviors rated by others	● Moderate
Innovation/resistance to change	● (+) For resistance to change	● Small
	● (+) For innovation	● Small
	• Curvilinear	• Strongest for those under age 35 compared to over age 35
OCB[a]/CWB[b]	● (−) For counterproductive work behaviors	● Small
	• Curvilinear	• Strongest for those over 40 and lowest for those under 25
	● (+) For organizational citizenship behaviors	
	• Directed at tasks	● Small
		• Moderate
Absenteeism	● (−) For tardiness and absenteeism	● Moderate
Safety behavior	● (+) For safety compliance	● Small
Attitudes	● (+) For job satisfaction, job involvement, intent to stay	● Small
	● (+) For organizational commitment	● Moderate
	● (−) For satisfaction with promotion	● Strong
Motives	● No effect for social motives	● None
	● No effect for importance of work relative to family	● None
	• Curvilinear	• Work–family conflict highest for middle age compared to younger and older workers
	● (+) For intrinsic motives	● Small
	● (+) For autonomy needs	● Moderate
	● (−) For growth, security, and extrinsic motives	● Small

Aging Mind: Facets and Levels of Analysis

Shu-Chen Li, Chair of Lifespan Developmental Neuroscience, Technische Universität (TU) Dresden, Dresden, Germany

Published by Elsevier Ltd.

Abstract

Basic cognitive mechanisms, such as the abilities to briefly maintain, focus, and process information decline gradually as people get older. These phenomena have attracted much public and research attention. Many subfields of cognitive aging research have been advancing rapidly, but mostly in an independent disintegrated fashion until the late 1990s. The first decade of the twenty-first century has seen much more integrated research efforts that help advanced out understandings about the links between the aging mind and aging brain. This article reviews various aspects of aging cognition occurring at the behavioral, information processing, and neurobiological levels, and describes general theoretical considerations aimed at integrative research across different fields.

A Zeitgeist in Search for Interdiscipline Integration

Throughout most of the last century, much of the basic research on cognition has progressed in a rather segregated fashion, with differences in experimental paradigms, methodological, and theoretical orientations together with traditional discipline boundaries setting the dividing lines. Disintegrated research pursuits as such are common, as most endeavors in early stages of research development are first devoted to the discoveries of unique new phenomena and the constructions of competitive theoretical interpretations. As the fields progress with ever-increasing empirical data and theories, integration is then necessary to provide a comprehensive understanding of the accumulated information.

Proposals to Integrate the Studies of Brain, Cognition, and Behavior

The need for developing overarching integrations across the many subfields of cognitive psychology and cognitive science is evident in the last decade of the twentieth century. Approaches for integrating the studies of brain, cognition, and behavior have been independently proposed by researchers of different specialization (**Figure 1** shows a summary diagram). For instance, researchers in the area of artificial intelligence have proposed *cross-domain integration* aiming at constructing comprehensive models to capture different domains of cognitive and behavioral functioning, such as perception, memory, learning, decision-making, emotion, and motivation (e.g., Newell, 1990). There is also the cognitive and computational neuroscience approach of *cross-level integration*, which aims at integrating empirical regularities and theories of cognition across the behavior, information processing, and biological levels (see Gazzaniga et al., 2009 for review). Others, built on Burnswik's and Gibson's earlier emphases on the embeddedness of behavior and cognition in the environmental context, have suggested a *human-ecology integration* stressing that functional adaptivity arising from the human–environment interaction must be considered en route to discoveries of universal principles of behavior and cognition (e.g., Gigerenzer et al., 1999; Shepard, 1995). In order to better capture dynamic exchanges between environmental support and biological resources across the life span, developmental psychologists (e.g., Baltes et al., 1999) have advocated a life span integrative approach to study behavior and cognition. Although these approaches differ in the questions they address, they complement, rather than exclude, each other, with the first two approaches focusing on different domains and levels of cognition and behavior within a person, and the last two focusing on the person–environment interactions and the evolutionary-ontogenetic dynamics that are the backbones of biocultural coconstruction of human development (Baltes et al., 2006; Li, 2003).

Cognitive Aging Phenomena Been Studied at Various Levels

Couched within the broader research context, the field of cognitive aging had also gone through a period of disintegrated research and is now orienting toward integration (*see* Cognitive Aging). Since the 1920s when the first studies on adult age differences in mental abilities were published, studies on cognitive aging have mostly been carried out independently by individual difference and cognitive experimental psychologists and neuroscientists at the behavioral, information processing, and biological levels (**Figure 2** gives an overview). Designs and results from animal neurobiological studies are not always readily testable in human cognitive studies, and vice versa. Therefore, until the recent advances with neuroimaging techniques (Cabeza, 2001), data and theories of cognitive aging have been mostly confined within their respective levels. The goal of this article is, thus, to review evidence of age differences in intelligence and basic cognitive processing in ways that highlight the many facets of aging mind and point out some recent attempts that have been undertaken since the 1990s to link previously less integrated areas of research.

Adult Age Differences in Intelligence

At the behavioral level, psychologists interested in how aging might affect individual differences in intelligence have taken the *psychometric approach*, which has a long tradition (dating back to classical works by Spearman, Galton, and Binet in the

Figure 1 A summary diagram of different approaches proposed in the 1990s for integrating the various fields of brain, cognitive, and behavioral sciences.

Figure 2 A summary diagram of various issues of aging mind addressed by researchers of different specialization at various levels. 1880s and early 1900s), and focused on the *measurement* of age differences in intellectual abilities. The existing psychometric data to date indicate that intellectual aging is multifaceted. Furthermore, aging effects can be observed at three aspects of the behavioral data, namely, performance level, variability, and covariation.

Differential Age-Gradients of Cognitive Mechanics and Pragmatics

Traditionally, two-component models of intelligence distinguish between fluid intelligence reflecting the operations of neurobiological 'hardware' supporting basic information-processing cognitive mechanics and crystallized intelligence reflecting the culture-based 'software' constituting the experience-dependent cognitive pragmatics (Baltes et al., 1999; Horn, 1982). **Figure 3** shows that the fluid mechanics, such as reasoning, spatial orientation, perceptual speed, and verbal memory, show gradual age-related declines starting at about the 40s; while other abilities indicating the crystallized pragmatics, such as number and verbal abilities, remain relatively stable up until the 60s (e.g., Schaie and Willis, 1993). Furthermore, there have also been some recent ongoing theoretical and empirical efforts devoted toward expending the concepts of cognitive mechanics and pragmatics. In addition to the efficacy of information processing, cognitive mechanics also encompasses the optimal allocation of cognitive resources (e.g., Li et al., 2001b). The cognitive pragmatics has been expanded to include many other general as well as person-specific bodies of knowledge and expertise associated with the occupational, leisure, and cultural dimensions of life (e.g., Blanchard-Fields and Hess, 1996). One example is *wisdom*, the "expert knowledge about the world and fundamental pragmatics of life and human affair" that an individual acquires through his or her life history, that also includes an implicit orientation toward maximizing individual and collective well-being (Baltes and Staudinger, 2000).

Age-Related Increase in Variability and Covariation

In addition to age differences in the performance levels of the cognitive mechanics, behavioral data also point to age-related increases of performance variations within a person (e.g., Hultsch et al., 2000) and differences between individuals (for review see Nelson and Dannefer, 1992; *see* Age Stratification). Furthermore, much cross-sectional data show that as people age performances of different subscales of intelligence tests become more correlated with each other (e.g., Babcock et al., 1997), which has been taken as indications of less differentiated ability structure in old people.

Deficits in Basic Information-Processing Mechanisms

In light of age-related declines in psychometrically measured cognitive mechanics, the *information-processing approach* emerged from the rise of information theory and computers in the 1940s was advanced to *explain* age differences in fluid intelligence by identifying age differences in basic information-processing mechanisms. Thus far, age-related declines have been found in three main facets of information processing: people's abilities to keep information in mind, attend to relevant information and process information promptly are compromised with age.

Working Memory

Working memory (WM) refers to people's ability to simultaneously hold information in immediate memory while operating on the same or other information. Age-related decline in WM capacity has been obtained on a variety of experimental tasks including backward digit span, sentence span, and several types of computational span (e.g., Park et al., 1996; see **Figure 4(a)**). Age-related decline in WM capacity plays a role in many other cognitive activities where WM is implicated, ranging from long-term memory encoding and retrieval, syntactic processing, language comprehension, and reasoning (for review see Zacks et al., 2000).

Attentional and Inhibitory Mechanisms

Empirical data abound showing that old people have more problems attending to relevant information and ignoring irrelevant information. Negative age differences have been found in various selective and focus attention tasks along with the Stroop and proactive interference tasks (e.g., Lair et al., 1969). Age-related declines in attentional and inhibitory mechanisms have functional consequences on language comprehension, memory, problem solving, and other daily activities such as driving (see McDowd and Shaw, 2000 for review).

Processing Speed and Variability

Speed is a ubiquitous aspect of information processing. All information processing takes time, however fast it is. There is abundant evidence showing that older people are slower in responding comparing to young adults in almost every cognitive task in which processing speed is measured (see Figures 3 and 4(b)). Many correlational analyses showed that the observed age differences in fluid intelligence is greatly reduced or eliminated after controlling for individual differences in processing speed (see Salthouse, 1996 for review). Furthermore, other than processing speed, cognitive aging research over the last decade has consistently shown that aging-related decline in processing variability (fluctuations in trial-by-trial reaction times) adds additional unique effects in predicting individual differences in cognitive declines (Lövdén et al., 2007). Neurocomputational theory (Li et al., 2001b) as well as empirical evidence (see MacDonald et al., 2009, for review) suggest that aging-related declines in dopaminergic modulation (see **Figure 4(c)**) is also one contributing factor to age-related increase in processing variability.

Resource-Reduction Account

Given clear age-related declines in these fundamental aspects of information processing, the most prominent account for cognitive aging deficits thus far has been the general conceptual framework of age-related reduction in processing resources that are indicated by WM capacity, attention regulation, and processing speed (see Salthouse, 1991 for review). However, two major difficulties limit the resource-reduction theory. First, the different aspects of processing resources are *not* independent of each other. Second, the account itself is circular in nature: old people's lower proficiency in cognitive performance is assumed to be caused by a reduction in processing resources, and at the same time, poor performance is taken to be the indication of reduced processing resources. One way to avoid such circularity is to establish better correspondence between the proposed processing resources and their potential neurobiological underpinnings. Lest this be viewed only as reductionistic, it should be mentioned that psychometric data showing stronger trends of age-related decline in the biology-based fluid intelligence motivates the search for biological correlates. Experimental evidence of age-related decline in basic facets of information processing helps focusing the studies of brain aging on those aspects relevant to the affected information-processing mechanisms. Recent developments in cognitive and computational neurosciences have opened new revenues for studying the

functional relationships between behavioral manifestations of the aging mind and the biology of the aging brain.

The Aging Brain of the Aging Mind

At the neurobiological level, brain aging involves both neuroanatomical and neurochemical changes. Anatomically, there are structural losses in neurons and synaptic connections and reductions in brain atrophy (see Raz, 2000 for review). Neurochemically, there is evidence for deterioration in various neurotransmitter systems (Schneider et al., 1996 for review). However, progressive neuroanatomical degeneration resulting from cell death and reduced synaptic density is primarily characteristic of pathological aging such as Alzheimer's disease, and there is now evidence suggesting that milder cognitive problems occurring during normal aging are mostly due to neurochemical shifts in still-intact neural circuitry (Morrison and Hof, 1997; *see* Brain Aging (Normal): Behavioral, Cognitive, and Personality Consequences).

Attenuated Neuromodulation

Among different neurotransmitter systems, the catecholamines, including dopamine (DA) and norepinephrine (NE), are important neurochemical underpinnings of age-related cognitive impairments for several reasons. First, there is consensus for age-related decline in catecholaminergic function in the prefrontal cortex (PFC) and basal ganglia. Across the adult life span, dopaminergic function in the basal ganglia decreases by 5–10% each decade (see Schneider et al., 1996). Furthermore, many DA pathways in the basal ganglia are interconnected with the frontal cortex through the frontal-striatal circuits (Graybiel, 1990), hence are in close functional association with the PFC cognitive processes. Second, research over the last two decades suggests that catecholamines modulate the PFC's utilization of briefly activated cortical representations of external stimuli to circumvent constant reliance on environmental cues and to regulate attention to focus on relevant stimuli and appropriate responses (see Arnsten, 1998 for review). Third, there are many findings indicating, specifically, functional relationships between age-related deficits in the dopaminergic system and deficits in various aspects of information processing. For instances, reduced dopamine receptor density in old rats' nigrostriatum decreases response speed and increases reaction time variability (MacRae et al., 1988). Drugs that facilitate dopaminergic modulation alleviate WM deficits of aged monkeys who suffer from 50% dopamine depletion in their PFC (see Arnsten, 1998 for review). In humans, age-related attenuation of dopamine D2 receptor's binding mechanism is associated with declines in processing speed and episodic memory (see Bäckman et al., 2006 for review).

Reduced Hemispheric Asymmetry

In addition to changes in the aging brain's neurochemical environment, recent neuroimaging evidence suggests that cortical information processing in different regions of the brain becomes less differentiated as people age, phenomena that parallel the behavioral findings of less differentiated ability structure in old people. In comparison to the more clearly lateralized cortical information processing in young adults, people in their 60s and beyond showed bilateralized (bihemispheric) activity during retrieval (e.g., Cabeza et al., 1997; Cabeza, 2001) and during both verbal and spatial WM tasks (Reuter-Lorenz et al., 2000).

Integrating the Facets and Levels of the Aging Mind

Faced with the various facets of the aging mind across the different levels, the various subfields of cognitive aging research are ever more inclined to and in need of overarching frameworks for integration (cf Stern and Carstensen, 2000). Some integrative research undertakings along the four general approaches for integrating the studies of brain, cognition, and behavior sciences have already been underway.

With respect to better integrating the human–environment exchange and the evolutionary-ontogenetic dynamics, at a macro level some researchers embedded issues of cognitive aging within a metatheoretical framework of biological and cultural coevolution for studying life span human development (*see* Lifespan Development: Evolutionary Perspectives). While the benefits of evolutionary selection and the efficacy of neurobiological implementations of the mind decrease with aging, the needs for environmental-cultural support increases. In this systemic functional framework it is important for future research to investigate how declines in cognitive resources may be compensated by the individual's more selective allocations of these resources to different task domains and by cultural-environmental supports such as cognitive training (e.g., Dixon and Bäckman, 1995; K.Z.H. Li et al., 2001a). At a more specific level, other researchers have also suggested an environmental support perspective for understanding age differences in episodic memory and attentional mechanisms. Better environmental stimulus and contextual supports are helpful in overcoming age-related deficits in effortful self-initiated processes implicated in various memory and attentional tasks (e.g., Craik, 1986; Park and Shaw, 1992).

Regarding better integrating different domains and levels of behavior and cognition within the person, some researchers have started to work toward bridging the gaps between age-related declines in basic memory and attentional processes and higher-level cognitive function, such as language comprehension (e.g., Light and Burke, 1988; Burke, 1997). Regarding cross-level integration, there actually have been a few classical proposals trying to relate individual differences in the performance level, variance and covariation of intellectual functioning with individual differences in general brain energy (Spearman, 1927) and to link age-related cognitive aging deficits with increased neuronal noise (e.g., Welford, 1965). However, these long-range brain-behavior links could not be specified with more details in early research. It has only recently become possible to investigate these links more explicitly in cognitive and computational neurosciences. There is now some consensus for associations between PFC dysfunctions and aging-related cognitive impairments (West, 1996). However, details of the functional relationships between PFC impairments, aging attenuated neuromodulation, the distribution of information processing across different neural circuitry, and

various behavioral manifestations of cognitive aging deficits await further explications. Recently, one computational neuroscience approach has been undertaken to explore the links between age-related declines in neuromodulatory mechanisms innervating the PFC, noisier neural information processing, and adult age differences in episodic memory, interference susceptibility, performance variability, and covariation (e.g., Li et al., 2001b; Li, 2002). Empirical evidence accumulated during the first decade of the twenty-first century, support this theory and indicates that aging-related declines in neuromodulation, particularly the catecholamines, contribute to various aspects of cognitive deficits, ranging from episodic memory (e.g., Li et al., 2013; Papenberg et al., 2013), WM, and processing speed and fluctuations (see Bäckman et al., 2006, 2010 for reviews).

These integrative research orientations have different advantages and disadvantages. While theoretical considerations about environmental and evolutionary impacts on the aging mind at the metatheoretical level have the strength in providing overarching organizations, they need to be complemented by more information processing and neurobiologically oriented approaches to generate predictions that are more amenable for direct empirical validations. In the process of coevolving a range of related fields, there may not be a 'right' level for integration; rather there is the task to supplement and balance the weaknesses and strengths of different approaches.

Conclusion

The average life expectancy in most industrialized countries has been increasing from an average of about 45 years in 1900 to about 75 years by the end of the twentieth century (Oeppen and Vaupel, 2002). According to the United Nation's 2011 report on world population prospects, the number of people aged 65 years or older will outnumber children under age of 5 years before 2020 (WHO, 2011). A major task for cognitive aging research in the twenty-first century is to identify the causes of and methods to minimize or compensate these cognitive declines, so that the blessings of improved physical health and extended life expectancy in old age could be accompanied by sound aging mind. Attempts to achieve this challenging task require collective contributions of studies from the various subfields of cognitive aging research, ranging from individual difference-based psychometric and behavioral experimental studies to cognitive and computational neurosciences in the future. Furthermore, research on the aging mind necessarily entails an applied orientation; therefore, future research also needs to include more specific focuses on identifying age-relevant knowledge, aging-friendly social and environmental contexts, and aging-rectifying training programs to help old people better allocate and compensate their declining cognitive resources.

Abstract

Theories of aging described include Erikson's stage theory, Baltes' selection, optimization, and compensation theory, Schaie and Willis' stage theory of cognition, as well as the coconstructive perspective. Current views on successful, normal, and pathological aging are also described.

Introduction

There have been few comprehensive theories of psychological development that have fully covered the period of adulthood (Schaie, 2013; Schaie and Willis, 1999). The broadest approaches have been those of Erik Erikson's stage theory (1982; Erikson et al., 1986), and the dialectical life span theory of Paul Baltes (1993). Erikson's stage theory has also been expanded for the period of adulthood and old age by Schaie and Willis (1999, 2000; Willis and Schaie, 2006).

Baltes' selection, optimization, and compensation (SOC) theory argues that gains and losses occur at every life stage, but that in old age losses far exceed the gains. Baltes considers evolutionary development to be incomplete for the very last stage of life, during which societal supports no longer fully compensate for declines in physiological infrastructure and losses in behavioral functionality (see Baltes, 1987; Baltes and Smith, 1999; Baltes et al., 1999). SOC, however, can also be seen as strategies of life management, and thus may be indicators of successful aging (Baltes and Freund, 2003). For a fuller exposition of SOC theory and review of relevant empirical studies, see Riediger et al. (2006).

The SOC theory has recently been expanded to a coconstructionist biosocial theory (Baltes and Smith, 2004; Willis and Schaie, 2006; see below). Theoretical models limited to the domain of cognition have also been proposed by Schaie and Willis (1977–78; 2000; Willis and Schaie, 2006), and by Sternberg (1985). I will here describe more fully, as examples, the Eriksonian, and the Schaie and Willis stage theories, as well as the more recent coconstructive theory.

Finally, I will then briefly discuss the distinction between successful, normal, and pathological aging, which is currently exerting a major influence on theories and research in life span developmental psychology.

Erikson's Stage Model

Traditional psychodynamic treatments of the life span have been restricted primarily to the development of both normal and abnormal personality characteristics. With the exception of some ego psychologists (e.g., Loevinger, 1976), however, Erik Erikson remains the primary theorist coming from a psychoanalytic background who has consistently pursued a life span approach. Although Erikson's most famous concept, the identity crisis, is placed in adolescence, the turmoil of deciding 'who you are' continues in adulthood, and identity crises often recur throughout life, even in old age (Erikson, 1979). Moreover, Erikson (1982) takes the position that "human development is dominated by dramatic shifts in emphasis."

In his latest writing, Erikson redistributed the emphasis on the various life stages more equitably. He argued that the question of greatest priority in the study of ego development is "how, on the basis of a unique life cycle and a unique complex of psychosocial dynamics, each individual struggles to reconcile earlier themes in order to bring into balance a lifelong sense of trustworthy wholeness and an opposing sense of bleak fragmentation" (Davidson, 1995; Erikson et al., 1986; Goleman, 1988).

The *intimacy crisis* is the primary psychosocial issue in the young adult's thoughts and feelings about marriage and family. However, recent writers suggest that this crisis must be preceded by identity consolidation, which is also thought to occur in young adulthood (cf Pals, 1999).

The primary issue of middle age, according to Erikson, is *generativity versus stagnation* (see McAdams and de St. Aubin, 1998; Snarey et al., 1987). Broadly conceived, *generativity* includes the education of one's children, productivity and creativity in one's work, and a continuing revitalization of one's spirit that allows for fresh and active participation in all facets of life. Manifestations of the generativity crisis in midlife are career problems, marital difficulties, and widely scattered attempts at 'self-improvement.'

Successful resolution of the generativity crisis involves the human virtues of caring, giving, and teaching in the home, on the job, and in life in general. In Erikson's view of ego development, the final years of life mark the time of the *integrity versus despair crisis*, when individuals look back over their lives (Haight et al., 1994) and decide that they were well ordered and meaningful (integrated) or unproductive and meaningless (resulting in despair).

Those who despair approach the end of life with the feeling that death will be one more frustration in a series of failures. In contrast, the people with integrity accept their lives (including their deaths) as important and on the whole satisfying. In a sense, ego integrity is the end result of the life-long search for ego identity, a recognition that one has coped reasonably successfully with the demands of both the id and society (Erikson, 1979, 1982; Whitbourne, 1996). Once old age is reached, it may be most advantageous for the person to rigidly maintain this identity (Tucker and Desmond, 1998).

The final stage of life includes an exploration of personal grounds for faith. Erikson points out that the aged share with infants what he calls the 'numinous' or the experience of the 'ultimate other.' For the infant, this particular experience was provided by its mother. By contrast, the experience of ultimate confidence is provided for the older person by the confirmation of the distinctiveness of their integrated life and by its impending transcendence (Erikson, 1984).

A formal investigation of the progression through the Eriksonian stages from young adulthood into midlife has been conducted by administering an inventory of psychosocial development to three cohorts of college students, followed up after 11 and 22 years (Whitbourne et al., 1992). This study showed not only inner psychological changes as postulated by Erikson, but also effects of exposure to particular historical, cultural, and social realities of the environment.

As attainment of higher stages was observed, there also appeared to be further resolution of the earlier stages of development, suggesting a process of continuous reorganization, beyond the stage-specific issues confronted by a given individual. The latter study also raises the possibility that the sequencing of Erikson's stages may not be unidirectional, and it further suggests cohort differences that imply less-favorable resolution of the ego integrity versus despair crisis during the decade of the 1980s (Whitbourne and Connolly, 1999).

Schaie and Willis' Stage Theory of Cognition

Schaie and Willis (1999, 2000) use findings from their research on adult intellectual development to formulate seven adult stages. They argue that while Piaget's childhood stages describe increasing efficiency in the acquisition of new information, it is quite doubtful that adults progress beyond the powerful methods of science (formal operations) in their quest for knowledge. Therefore, if one is to propose adult stages, they should not be further stages of acquisition; but, instead, such stages should reflect different uses of intellect.

In young adulthood, for example, people typically switch their focus from the acquisition to the application of knowledge, as they use what they know to pursue careers and develop their families. This is called the *achieving* stage. It represents most prominently the application of intelligence in situations that have profound consequences for achieving long-term goals. The kind of intelligence exhibited in such situations is similar to that employed in educational tasks, but it requires careful attention to the possible consequences of the problem-solving process.

Young adults who have mastered the cognitive skills required for monitoring their own behavior and, as a consequence, have attained a certain degree of personal independence, which will next move into a stage that requires the application of cognitive skills in situations involving social responsibility. Typically, the *responsible* stage occurs when a family is established and the needs of spouse and offspring must be met. Similar extensions of adult cognitive skills are required as responsibilities for others are acquired on the job and in the community.

Some individuals' responsibilities become exceedingly complex. Such individuals – presidents of business firms, deans of academic institutions, officials of churches, and a number of other positions – need to understand the structure and the dynamic forces of organizations. They must monitor organizational activities not only on a temporal dimension (past, present, and future), but also up and down the hierarchy that defines the organization. They need to know not only the future plans of the organization, but also whether policy decisions are being adequately translated into action at lower levels of responsibility. Attainment of the *executive* stage, as a variation on the responsibility stage, depends on exposure to opportunities that allow the development and practice of the relevant skills (Avolio, 1991; Smith et al., 1994).

In the later years of life, beyond the age of 60 or 65, the need to acquire knowledge declines even more, and executive monitoring is less important because frequently the individual has retired from the position that required such an application of intelligence. This stage, *reintegration*, corresponds in its position in the life course to Erikson's stage of ego integrity. The information that elderly people acquire and the knowledge they apply becomes a function of their interests, attitudes, and values. It requires, in fact, the *reintegration* of all of these. The elderly are less likely to 'waste time' on tasks that are meaningless to them. They are unlikely to expend much effort to solve a problem unless that problem is one that they face frequently in their lives. This stage frequently includes a selective reduction of interpersonal networks in the interest of reintegrating one's concern in a more self-directed and supportive manner (cf Carstensen, 1993; Carstensen et al., 1997).

In addition, efforts must be directed toward planning how one's resources will last for the remaining 15–30 years of postretirement life that are now characteristic for most individuals in industrialized societies. These efforts include active planning for that time when dependence upon others may be required to maintain a high quality of life in the face of increasing frailty. Such efforts may involve changes in one's housing arrangements, or even one's place of residence, as well as making certain of the eventual availability of both familial and extrafamilial support systems. The activities involved in this context include making or changing one's will, drawing up advanced medical directives and durable powers of attorney, as well as creating trusts or other financial arrangements that will protect resources for use during the final years of life or for the needs of other family members.

Although some of these activities involve the same cognitive characteristics of the responsible stage, these objectives involved are far more centered upon current and future needs of the individual rather than the needs of their family or of an organizational entity. Efforts must now be initiated to reorganize one's time and resources to substitute a meaningful environment, often found in leisure activities, volunteerism, and involvement with a larger kinship network. Eventually, however, activities are also engaged in to maximize quality of life during the final years, often with the additional objective of not becoming a burden for the next generation. The unique objective of these demands upon the individual represent an almost universal process occurring at least in the industrialized societies, and

designation of a separate *reorganizational* stage is therefore warranted.

The skills required for the reorganizational stage require the maintenance of reasonably high levels of cognitive competence. In addition, maintenance of flexible cognitive styles are needed to be able to restructure the context and content of life after retirement, to relinquish control of resources to others and to accept the partial surrender of one's independence (Schaie, 1984, 2005).

Many older persons reach advanced-old age in relative comfort and often with a clear mind albeit a frail body. Once the reintegrative efforts described above have been successfully completed, yet one other stage is frequently observed. This last stage is concerned with cognitive activities by many of the very old that occur in anticipation of the end of their life. This is a *legacy-creating* stage that is part of the cognitive development of many, if not all, older persons. This stage often begins by the self- or therapist-induced effort to conduct a life review (Butler et al., 1998). For the highly literate and those successful in public or professional life, this will often include writing or revising an autobiography (Birren et al., 1995; Birren and Schroots, 2006).

There are also many other more mundane legacies to be left. Women, in particular, often wish to put their remaining effects in order, and often distribute many of their prized possessions to friends and relatives, or create elaborate instructions for distributing them. It is not uncommon for many very old people to make a renewed effort at providing an oral history or to explain family pictures and heirloom to the next generation. Last, but not least, directions may be given for funeral arrangements, occasionally including donation of one's body for scientific research, and there may be a final revision of one's will.

The Coconstructive Perspective

Both neurobiological and sociocultural influences on development have long been recognized. Coevolutionary theorists (Dunham, 1991; Tomasello, 1999) suggest that both biological and cultural evolution has occurred and that recent, cohort-related advances in human development in domains such as intelligence can be attributed largely to cumulative cultural evolution. Cultural activities impact the environment, thereby influencing mechanisms such as selection processes, and thus allow humans to codirect their own evolution (Cavalli-Sforza and Feldman, 1981; Dunham, 1991). Baltes et al. (1997), Li (2003), Li and Freund (2005) Baltes' and his colleagues (1997; Li, 2003; Li and Freund, 2005) coconstructionist approach imposes a life span developmental perspective on coevolutionary theory and provides principles regarding the timing of the varying contributions of neurobiology and culture at different developmental periods and across different domains of functioning. Three principles have been proposed regarding the relative contributions of biology and culture influences across the life span:

1. Beneficial effects of the evolutionary selection process occur primarily in early life and are less likely to optimize development in the later half of life.
2. Further advances in human development depend on ever-increasing cultural resources. From a historical perspective, increases in cultural resources have occurred via cumulative cultural evolution and have resulted in humans reaching higher levels of functioning. At the individual level, increasing cultural resources are required at older ages for further development to occur or to prevent age-related losses.
3. The efficacy of increasing cultural resources is diminished in old age, due to decline in neurobiological functions.

Li (2003) proposes a triarchic view of culture involving three aspects of culture that are related to the coconstructionist perspective: resource, process, and developmental relevancy. Culture as social resources involves the knowledge, values, and material artifacts accumulated by a society and transmitted to future generations; these resources continue to develop and change through cumulative cultural evolution (Tomasello, 1999). Expanding upon Li's triarchic view of cultural domains, Willis and Schaie (2006) view accumulated cultural resources as being represented by structural variables such as educational level, occupational status, and ability level. These variables reflect the individual's acquisition and accumulation of cultural knowledge and skills primarily during the first half of adulthood.

Culture as ongoing social process involves the routines, habits, and performances of the individual in daily life that take place in the individual's proximal developmental context and that are shaped by the momentarily shared social reality (Li, 2003). The third component of developmental relevancy suggests that the impact of particular cultural resources and processes on an individual is partially determined by the individual's developmental stage, which has also termed the 'developmental niche' (Gauvain, 1998; Super and Harkness, 1986). The coconstructive perspective may be particularly useful in understanding the interplay risk and protective factors that influence cognitive aging.

Successful, Normal, and Pathological Aging

It is readily apparent that there are vast individual differences in patterns of psychological changes from young adulthood through old age. Scrutiny of a variety of longitudinal studies of psychological aging (cf Schaie and Hofer, 2001) suggest that four major patterns will describe most of the observed aging trajectories, although further subtypes could, of course, be considered (Schaie, 2006). These patterns would classify individuals into those who age successfully (the supernormals), those who age normally, those who develop mild cognitive impairment, and finally those who become clinically diagnosable as suffering from dementia.

The most common pattern is what we could denote as the *normal aging* of psychological functions. This pattern is characterized by most individuals reaching an asymptote in early midlife, maintaining a plateau until the late 50s or early 60s, and then showing modest decline on most cognitive abilities through the early 80s, with more marked decline in the years prior to death (cf Bosworth et al., 1999). They also tend to become more rigid and show some changes on personality

traits in undesirable directions (Schaie et al., 2004). Among those whose cognitive aging can be described as normal, we can distinguish two subgroups. The first include those individuals who reach a relatively high level of cognitive functioning who even if they become physically frail can remain independent until close to their demise. The second group who only reach a modest asymptote in cognitive development, on the other hand, may in old age require greater support and be more likely to experience a period of institutional care.

A small subgroup of adults experience what is often described as *successful aging* (Fillit et al., 2002; Rowe and Kahn, 1987). Members of this group are often genetically and socio-economically advantaged, they tend to continue cognitive development later than most and typically reach their cognitive asymptotes in late-midlife. While they too show some very modest decline on highly speeded tasks, they are likely to maintain their overall level of cognitive functioning until shortly before their demise. They are also likely to be less neurotic and more open to experience than most of their age peers. These are the fortunate individuals whose active life expectancy comes very close to their actual life expectancy.

The third pattern, *mild cognitive impairment* (MCI; Petersen et al., 1999), includes that group of individuals who, in early old age, experience greater than normative cognitive declines. Various definitions, mostly statistical, have been advanced to assign membership to this group. Some have argued for a criterion of one *SD* of performance compared to the young adult average, while others have proposed a rating of 0.5 on a clinical dementia rating scale, where 0 is normal and 1.0 is probable dementia. Earlier on, the identification of MCI required the presence of memory loss, in particular. However, more recently, the diagnosis has been extended to decline in other cognitive abilities. There has also been controversy on the question whether individuals with the diagnosis of MCI inevitably progress to dementia, or whether this group of individuals represents a unique entity; perhaps one could denote them as the *unsuccessful aging* (cf Petersen, 2003).

The final pattern includes those individuals who in early or advanced old age are diagnosed as suffering from *dementia*. Regardless of the specific cause of the dementia, these individuals have in common dramatic impairment in cognitive functioning. However, the pattern of cognitive change, particularly in those whose diagnosis at postmortem turns out to be Alzheimer's disease, is very different from the normal aging. When followed longitudinally, at least some of these individuals show earlier decline, perhaps starting in midlife.

Psychologists and members of the health- and health-related professions in general, have often assumed that age-related cognitive losses as well as other behavioral deficits inevitably accompany the aging process. Although there is some controversy over the possibility of disease-free aging, it is still important to distinguish between biological changes that occur in many individuals with increasing age and the presence of specific physiological or psychological pathologies that may not be age-related even though they occur with greater frequency at advanced ages (cf Solomon, 1999). The fact remains that chronic disease, often associated with aging, may have their origin in genetic predispositions, and become clinically relevant over a wide age range. While cognitive decline affects significant portions of the elderly population, its symptomatology is often confused with that associated with metabolic disturbances, and/or sensory and metabolic disturbances. Indeed, there is no compelling reason to believe that selective age-related ability-declines will inevitably lead to dementia, nor that they cannot be addressed by cognitive training or psychotherapy in many individuals (cf Willis, 1996).

Abstract

Agnosia is a fascinating condition in which, as a consequence of acquired brain damage, patients lose the ability to recognize familiar stimuli, despite normal perception of those stimuli. For example, when encountering the faces of familiar persons such as family members or close friends, a patient with agnosia is unable to identify those persons, or even to recognize that they are familiar. Agnosia can affect recognition of stimuli in any sensory modality, including visual, auditory, and tactile, although visual agnosia is the most common form of the disorder. Careful scientific study of agnosia has provided many important new insights into the manner in which the human brain acquires, maintains, and utilizes various types of knowledge.

Agnosia is a fascinating condition in which, as a consequence of acquired brain damage, patients lose the ability to recognize familiar stimuli, despite normal perception of those stimuli. For example, when encountering the faces of familiar persons such as family members or close friends, a patient with agnosia is unable to identify those persons, or even to recognize that they are familiar. A patient may look at pictures of entities such as animals or tools, and have no idea what the stimuli are. Or a patient may hear well-known sounds, such as a fire siren or a ringing phone, and not be able to identify the sounds or understand their meaning (despite being able to hear the sounds normally). Agnosia is a rare condition, and its clinical presentation borders on the bizarre; nonetheless, careful scientific study of agnosia has provided many important insights into the brain mechanisms important for learning, memory and knowledge retrieval.

Types of Knowledge and Levels of Knowledge Retrieval

Before discussing agnosia, it is important to explain some crucial differences in the types of knowledge that are processed by the brain, and how different task demands influence the mechanisms the brain uses to retrieve knowledge. To begin with, there is a dimension of specificity: knowledge can be retrieved at different levels of specificity, ranging from very specific to very general. Consider the following example: Knowledge about a unique horse ('Little Buck,' a sorrel roping horse) is specific and unique, and is classified at the subordinate level; less specific knowledge about horses (four-legged animals that gallop, used by cowboys; of which Little Buck is an example) is classified at the basic object level; and even less specific knowledge about living things (things that have life, of which horses and Little Buck are examples) is classified at the superordinate level.

Pragmatically, the level at which knowledge is retrieved depends on the demands of the situation, and those demands are different for different categories of entities. In everyday life, for example, it is mandatory that familiar persons be recognized at the unique level – e.g., that's 'President Clinton,' or that's 'my father Ned.' It is not sufficient, under most conditions, to recognize such entities only at more nonspecific levels – e.g., that's a 'world leader,' or that's 'an older man.' For other types of entities, recognition at the basic object level is sufficient for most purposes – e.g., that's a 'screwdriver,' or that's a 'stapler'; here, there is no need to recognize individual, unique screwdrivers and staplers in order for practical interactions with the entity to be productive.

One other critical distinction is between recognition, on the one hand, and naming, on the other. The two capacities are often confused. It is true that recognition of an entity, under normal circumstances, is frequently indicated by naming (e.g., 'stapler'; 'Little Buck'; 'siren'). However, there is a basic difference between knowing and retrieving the meaning of a concept (its functions, features, characteristics, relationships to other concepts), and knowing and retrieving the name of that concept (what it is called); moreover, this difference is honored by the brain. For example, brain damage in the left inferotemporal region can render a patient incapable of naming a wide variety of stimuli, while leaving unaffected the patient's ability to recognize those stimuli (Damasio et al., 1996). For the examples of 'Little Buck' and 'siren' cited above, the patient may produce the descriptions of 'that's my sorrel roping horse that I bought 2 years ago and now lives on my dad's ranch,' and 'that's a loud sound that means there's an emergency; you should pull your car over to the side of the road.' Both responses indicate unequivocal recognition of the specific entities, even if their names are never produced. In short, it is important to maintain a distinction between recognition, which can be indicated by responses signifying that the patient understands the meaning of a particular stimulus, and naming, which may not, and need not, accompany accurate recognition (Caramazza and Shelton, 1998; Gainotti et al., 1995; Pulvermuller, 1999).

The Term 'Agnosia'

The term 'agnosia' signifies 'lack of knowledge,' and denotes an impairment of recognition. Traditionally, two types of

agnosia have been described (Lissauer, 1890). One, termed associative agnosia, refers to a failure of recognition that results from defective retrieval of knowledge pertinent to a given stimulus. Here, the problem is centered on memory: the patient is unable to recognize a stimulus (i.e., to know its meaning) despite being able to perceive the stimulus normally (e.g., to see shape, color, texture; to hear frequency, pitch, timbre; and so forth). The other type of agnosia is termed apperceptive, and refers to a disturbance of the integration of otherwise normally perceived components of a stimulus. Here, the problem is centered more on perception: the patient fails to recognize a stimulus because the patient cannot integrate the perceptual elements of the stimulus, even though those individual elements are perceived normally. It is important to emphasize that the nuclear feature in designating a condition as 'agnosia' is that there is a recognition defect that cannot be attributed simply or entirely to faulty perception.

The terms associative and apperceptive agnosia have remained useful, even if the two conditions do have some overlap. It is usually possible to classify a patient with a recognition impairment as having primarily a disturbance of memory (associative agnosia), or primarily a disturbance of perception (apperceptive agnosia). Not only does this classification have important implications for the management of such patients (e.g., what rehabilitation should be applied), but it also maps on to different sites of neural dysfunction. For example, in the visual modality, associative agnosia is strongly associated with bilateral damage to higher-order association cortices in the ventral and mesial occipito-temporal regions, whereas apperceptive agnosia is associated with unilateral or bilateral damage to 'earlier,' more primary visual cortices. This being said, though, the fact remains that separating associative and apperceptive agnosia can be difficult, which underscores the fact that the processes of perception and memory are not discrete. Rather, they operate on a physiological and psychological continuum, and it is simply not possible to demarcate a specific point at which perceptual processes end and memory processes begin (Damasio et al., 1990; Tranel and Damasio, 1996).

In principle, agnosia can occur in any sensory modality, relative to any type of entity or event. In practice, however, some types of agnosia are considerably more frequent. Visual agnosia, especially agnosia for faces (prosopagnosia), is the most commonly encountered form of recognition disturbance. The condition of auditory agnosia is rarer, followed by the even less frequent tactile agnosia.

Visual Agnosia

Definition

Visual agnosia is defined as a disorder of recognition confined to the visual realm, in which a patient cannot arrive at the meaning of some or all categories of previously known nonverbal visual stimuli, despite normal or near-normal visual perception and intact alertness, attention, intelligence, and language. Typically, patients have impairments both for stimuli that they learned prior to the onset of brain injury (known as 'retrograde' memory), and for stimuli that they would normally have learned after their brain damage (known as 'anterograde' memory).

Subtypes

Prosopagnosia

The study of face processing has remained a popular topic in neuropsychology for many decades, dating back to the pioneering work of Bodamer, Hecaen, Meadows, and others (for historical reviews, see Benton, 1990; De Renzi, 1997). Faces are an intriguing class of stimuli (Damasio et al., 1982; Young and Bruce, 1991). They are numerous and visually similar, and yet we learn to recognize individually as many as thousands of distinct faces during our lifetime; and not only can we learn many individual faces, but we can recognize them from obscure angles (e.g., from the side), attended with various artifacts (e.g., glasses, hockey helmet), after aging has radically altered the physiognomy, and under many other highly demanding conditions. Also, faces convey important and unique social and emotional information, providing clues about the emotional state of a person, or about potential courses of social behavior (e.g., approach or avoidance) (see Darwin, 1955 [1872]/1955 [1872]; Adolphs et al., 1998). And there are a number of remarkable cross-cultural and cross-species consistencies in face processing (cf Ekman, 1973; Fridlund, 1994), which underscore the crucial and fundamental importance of this class of stimuli.

The inability to recognize familiar faces is known as prosopagnosia (face agnosia), and it is the most frequent and well established of the visual agnosias (Damasio et al., 1990; Farah, 1990). The face recognition defect in prosopagnosia typically covers both the retrograde and anterograde compartments; respectively, patients can no longer recognize the faces of previously known individuals, and are unable to learn new ones. They are unable to recognize the faces of family members, close friends, and, in the most prototypical instances, even their own face in a mirror. Upon seeing those faces, the patients experience no sense of familiarity, no inkling that those faces are known to them, i.e., they fail to conjure up consciously any pertinent information that would constitute recognition. The impairment is modality-specific, however, being entirely confined to vision. For example, when a prosopagnosic patient hears the voices of persons whose faces were unrecognized, the patient will instantly be able to identify those persons accurately.

As noted above with regard to agnosia in general, prosopagnosia must be distinguished from disorders of naming, i.e., it is not an inability to name faces of persons who are otherwise recognized as familiar. There are numerous examples of face naming failure, from both brain-injured populations and from the realm of normal everyday experience, but in such instances, the unnamed face is invariably detected as familiar, and the precise identity of the possessor of the face is usually apprehended accurately. Consider, for example, the following common type of naming failure: you encounter someone whom you recently met, and cannot remember that person's name: you can remember when and where you met the person, who introduced you, and what the person does for a living – in short, you recognize the person normally. In prosopagnosia, the defect sets in at the level of recognition.

The recognition impairment in prosopagnosia occurs at the most subordinate level, i.e., at the level of specific identification of unique faces. Prosopagnosics are fully capable of recognizing faces as faces, i.e., performance is normal at more superordinate, nonspecific levels. Also, most prosopagnosics can recognize facial emotional expressions (e.g., happy, angry), and can make accurate determinations of gender and age based on face information (Humphreys et al., 1993; Tranel et al., 1988). These dissociations highlight several intriguing separations in the neural systems dedicated to processing different types of conceptual knowledge, such as knowledge about the meaning of stimuli, knowledge about emotion, and so on. In fact, these neural systems can be damaged in reverse fashion: for example, bilateral damage to the amygdala produces an impairment in recognizing facial emotional expressions, but spares the ability to recognize facial identity (Adolphs et al., 1995).

Although the problem with faces is usually the most striking, it turns out that the recognition defect in prosopagnosia is often not confined to faces. Careful assessment often reveals that the patient cannot recognize other visual entities at the normal level of specificity. The key determinants of whether other categories of stimuli are affected are (1) whether those stimuli are relatively numerous and visually similar, and (2) whether the demands of the situation call for specific identification. Whenever these conditions exist, prosopagnosics will tend to manifest deficits. For example, patients may not be able to identify a unique car, or a unique house, or a unique horse, even if they are able to recognize such entities at the basic object level, e.g., cars as cars, houses as houses, horses as horses. Similar to the problem with faces, they are unable to recognize the specific identity of a particular car, or house. These impairments underscore the notion that the core defect in prosopagnosia is the inability to disambiguate individual visual stimuli. In fact, cases have been reported in which the most troubling problem for the patient was in classes of visual stimuli other than human faces! For example, there was a farmer who lost his ability to recognize individual dairy (e.g., Holstein) cows, and a bird-watcher who became unable to tell apart various subtypes of birds (Assal et al., 1984; Bornstein et al., 1969).

Patients with face agnosia can usually recognize identity from movement. For example, upon seeing a distinctive gait of a familiar person, the patient can identify that person accurately, despite not knowing that person's face. This means not only that their perception of movement is intact, but also that they can evoke appropriate memories from the perception of unique patterns of movement. Conversely, patients with lesions in superior occipitoparietal regions (whose recognition of identity from form is normal, and hence do not have impaired face recognition) have defective motion perception and recognition. These findings underscore the separable functions of the 'dorsal' and 'ventral' visual systems, the dorsal one being specialized for spatial placement, movement, and other 'where' capacities; and the ventral one being specialized for form detection, shape recognition, and other 'what' capacities (Ungerleider and Mishkin, 1982). In prosopagnosia, the dysfunction is in the 'what' system.

One of the most intriguing findings to emerge in this area of research is that despite an inability to recognize familiar faces consciously, prosopagnosic patients often have accurate nonconscious (or covert) discrimination of those faces. This phenomenon has been studied using a psychophysiological index (the skin conductance response [SCR]) to measure nonconscious discrimination (Tranel and Damasio, 1985). SCRs were recorded while prosopagnosic patients viewed a series of face stimuli. The stimulus sets included faces that were well known to the patients, mixed in random order with faces the patients had never seen before. While viewing the faces, the patients produced significantly larger SCRs to familiar faces, compared to unfamiliar ones. This occurred in several experiments, using different types of familiar faces: in one, the familiar faces were family members and friends, in another, the familiar faces were famous individuals (movie stars, politicians), and in yet another, the familiar faces were persons to whom the patients had had considerable exposure after the onset of their condition, but not before. In sum, the patients showed nonconscious discrimination of facial stimuli they could not otherwise recognize, and for which even a remote sense of familiarity was lacking. These findings suggest that some part of the physiological process of face recognition remains intact in the patients, although the results of this process are unavailable to consciousness. The fact that the patients were able to show this type of discrimination for faces to which they had been exposed only after the onset of their condition is particularly intriguing, as it suggests that the neural operations responsible for the formation and maintenance of new 'face records' can proceed independently from conscious influence.

Category-Specific Visual Agnosia

Agnosia can develop for categories of stimuli other than faces, at levels above the subordinate, for example, at basic object level. For instance, patients may lose the ability to recognize animals or tools. This is generally referred to as visual object agnosia. The condition rarely affects all types of stimuli with equal magnitude (Farah and McClelland, 1991; Forde and Humphreys, 1999; Tranel et al., 1997; Warrington and Shallice, 1984). In one common profile of visual object agnosia, there is a major defect in categories of living things, especially animals, with relative or even complete sparing of categories of artifactual entities (e.g., tools and utensils). Less commonly, the profile is reversed, in that the patient cannot recognize tools/utensils but performs normally for animals (Tranel et al., 1997; Warrington and McCarthy, 1994). It has been shown that lesions in the right mesial occipital/ventral temporal region, and in the left mesial occipital region, are associated with defective recognition of animals; whereas lesions in the left occipital-temporal-parietal junction are associated with defective recognition of tools/utensils (Tranel et al. 1997).

Concluding Comment

Despite their relative rarity, agnosias have proved to be important 'experiments of nature,' and they have assisted with the investigation of the neural basis of human perception, learning, and memory. Careful study of agnosic patients over many decades, facilitated by the advent of modern neuroimaging techniques (computed tomography, magnetic resonance) and by the development of sophisticated experimental

neuropsychological procedures, has yielded important new insights into the manner in which the human brain acquires, maintains, and uses various of knowledge.

Editor's Note

Research into the disorders of perception following brain damage has advanced considerably since this article was first published. Current research focuses on the contribution of imaging methods to the precise definition of structural and functional changes in acquired and congenital visual agnosia; the specificity of the disorder of face recognition in prosopoagnosia; and the role of subtle deficits of primary visual processing; and the characteristics of agnosia in the tactile and auditory modality. Readers seeking entry to current literature on these topics will find the following useful: Avidan et al. (2014), Bridge et al. (2013), Cavina-Pratesi et al. (2010), Konen et al. (2011), Rezlescu et al. (2014), Saygin et al. (2010), Serino et al. (2014), Veronelli et al. (2014).

Abstract

As a way of thinking about politics and 'the political,' the concept of agonism emphasizes struggle, contest, and plurality. Originating in the *agōn* of ancient Greece, it has recently come to characterize a distinct branch of democratic theory. Combining insights derived from Nietzsche and Arendt with a poststructuralist ontology, contemporary agonists have staged a critical debate with normative theories that prioritize rational deliberation and consensus as the means and ends of democratic politics. This article surveys the ancient *agōn* as well as contemporary forms of agonism, using the former to pinpoint three axes of contingency that combine as an agonistic politics, and which continue to focus debates in democratic political theory today.

Overview

At once very old and very new, agonism originates in the athletic and oratorical contests of ancient Greece, while more recently it has emerged as a distinct branch of political theory. This article begins with an account of the ancient *agōn*, focusing on how it began as an aristocratic practice, which was later democratized, culminating in a type of contest, which was stretched between distinction and equality, thus creating a tension within the space of the *agōn* itself. Section The *Agōn* (Un)Bound draws on the work of Hannah Arendt, who identifies a further tension in the way the *agōn* was bounded as a threshold between an 'inside' and an 'outside,' which is also the point at which agonistic contest gives way to violence. Out of these tensions emerge what might be described as three axes of contingency, which will serve the purpose of mapping the contours of contemporary agonism. Section Staging the Contest surveys the context that has seen agonism reemerge as a way of staging critical encounters with normative theories that prioritize rational deliberation and consensus as the means and ends of democratic politics. Finally, Sections The Expressive Agon: Pluralization against Pluralism and The Pragmatic Agon: Agonism against Antagonism examine two of the main currents in contemporary agonistic political thought: the 'expressive' agonism of William E. Connolly and the 'pragmatic' agonism of Chantal Mouffe (Schaap, 2009).

The *Agōn* as 'Democratic Narcissus'

Contemporary agonists have borrowed the concept from thinkers such as Hannah Arendt and Friedrich Nietzsche, but, as Andreas Kalyvas points out, they have yet to engage with the *agōn* of the ancients, which is curious, because there is much to learn from this almost-forgotten history, particularly with respect to the tenuous, which is to say, contingently articulated relationship between agonism and democracy (2009: 16). Furthermore, beyond offering important insights into the concept itself – how it was constituted and configured – it also provides a way of pinpointing certain resonances between past and present, which can be used to explore the kinds of questions that the agonists of today are wrestling with.

In reconstructing this history, Kalyvas acknowledges that the task is hampered by the fragmented and partial nature of the evidence, but the evidence does suggest that the archaic Hellenic *agones*, or athletic games of the eighth and ninth centuries BC, probably retained links to older religious rituals and festivals (2009: 18). This was a world described by Nietzsche as one of 'combat and cruelty,' where 'combat is salvation and deliverance,' and where "the cruelty of the victory is the pinnacle of life's jubilation" (1994: 175). As a test of strength, courage and skill, the *agones* were a way of selecting the best among the best, with the process of selection itself restricted to a select few, for the contest was a "competitive aristocratic practice" (Kalyvas, 2009: 18).

Crucial to this staging of games was the public nature of the contest: the *agones* were public gatherings where the best prevailed by engaging in fair and open competition. Victory was rewarded in the form of recognition, praise and admiration, with heroic feats immortalized in poetry and sculpture. Conversely, to lose and suffer defeat was to endure shame and humiliation. The stakes were high but the prize was worth the risk, because the game was staged in front of an audience who would bestow adulation upon the victor, which leads Kalyvas to conclude that the 'psychic structure' of the archaic agon resembles the myth of Narcissus. In other words, the actions of the athlete were mirrored by the audience, and the act itself would be nothing without the presence of this assembly. Just as Narcissus' self-love is mediated by his reflection, so the self-love of the athletes was refracted through, and affirmed by, the shouts, gestures, and encouragement of spectators. As Kalyvas puts it, the *agōn* of the ancients was a "strategy for inducing others to love you so that you can love yourself through their love for you" (2009: 23).

So the *agōn* originates as a contest among equals in public space. But as noted already, it was a very select group of equals who gathered together in staging the games. Between the seventh and sixth centuries this changed as the *agōn* became more diffuse and diverse, no longer confined to athletic contests, and no more the preserve of a nobility. It is in this sense that Kalyvas charts the democratization of the *agōn*, which was staged in a variety of forms, including artistic, legal, rhetorical, philosophical, and musical contests. As more people from a diversity of social spheres began to participate in such

games, so the quasimartial displays of physical prowess gave way to public contests of words, a process described by Kalyvas as the "steady pacification of the agon" (2009: 23). The exemplary technique was rhetoric, whereby skilful speech takes the place of physical demonstration.

Without losing sight of the fact that the freedom of the Greek *polis* was accessible only to citizens, thereby excluding women and slaves, the democratization of the *agōn* also saw the meaning of excellence enlarged. The light of public adoration that had once illuminated the hero now had to radiate outwards to the *polis* itself, so that to excel in the space of agonistic contest was to contribute to the greatness, prosperity, and security of one's city and political community (Kalyvas, 2009: 24). Furthermore, unlike the spatial division between athlete and audience, which had characterized the archaic *agones*, now every spectator was – at least potentially – a player, and because the contest had become a more regular feature of public life, so losers could rise more easily to challenge again.

This transformation did not erase the original psychic structure of the *agōn*, however, which had but sedimented in the practice itself, which is why Kalyvas coins the phrase 'democratic narcissus.' As a public performance in pursuit of excellence, the democratic agon fused political equality to the aristocratic desire for distinction, with the result that citizens – driven by envy, enmity, and ambition – often resorted to deception, manipulation, and lies in order to succeed (Arendt, 2005: 16; Nietzsche, 1994). It was this inbuilt tension that gave rise to what Kalyvas describes as a 'counternarcissistic apparatus of power,' which was intended to protect democracy against its own excesses. One instrument of this apparatus was ostracism: to remove men who became too great and walked like gods among mere mortals. Another was tyrannicide, which allowed for the assassination of people deemed enemies of the public (Kalyvas, 2009: 28–30). Both aimed at protecting the agon. In the case of ostracism, against those who excelled to such an extent that they made the outcome of contest a foregone conclusion, thus rendering the spirit of the agon – a contest among equals – obsolete. As Nietzsche observed, the 'strange institution' of ostracism was a 'stimulant: the preeminent individual is removed to renew the tournament of forces' – there must always be more than one genius so that they 'incite each other to action' and "keep each other within certain limits" (1994: 178). In the case of tyrannicide, the agon was to be defended against tyrants who negated the spirit of fair and open contest by fixing the outcome or circumventing the rules. The purpose of these practices was to keep the contest alive by purging the *polis* of its internal enemies. But there was something else, something corrosive built into the very constitution of the Greek conception of agonistic struggle, and this, argues Arendt, would help to bring an end to the Hellenic world.

The *Agōn* (Un)Bound

Arendt uses Homer's poetry to construct a diagram of political struggle, which enables her to contrast two exemplary forms of political struggle – the *polis* and the *res publica* (republic), and to distinguish politics from violence. 'It would appear,' writes Arendt, that "the Greeks separated struggle – without which neither Achilles nor Hector would ever have made his appearance and been able to prove who he was – from the military world of war, in which brute force has its original home, and in so doing turned struggle into an integrating component of the *polis* and the political sphere" (Arendt, 2005: 171–172). This was the great achievement of the Greeks: the combat between Hector and Achilles was continually played out in the daily lives of citizens as they met in the *agora*, which was the hub of public life – the place where citizens gathered, assembled, and exchanged opinions. This was politics: struggle and rivalry whereby each is confronted by the presence of others.

But if the *agora* was the beating heart of the ancient *polis*, the *polis* itself was bounded in such a way that its contests could only be directed inwards, leading to an insular politics whereby struggle – in the agonistic sense – could not extend beyond the walls of the city. The oratorical contests staged in the *agora* involved a freedom that was not 'irrevocably bound' to a person's own point of view, and this, Arendt reminds us, is *phronēsis*, or the 'insight of the political man,' meaning "the greatest possible overview of all the possible standpoints and viewpoints from which an issue can be seen and judged" (2005: 168). And yet this freedom to see the world in its 'many-sidedness' was spatially delimited (2005: 170). Politics, as a contest of words among equals, begins and ends in the bounded space of the *polis*. For the Greeks, war could not be political because it presupposes brute force, command and obedience, and even negotiations between warring states or city-states could not be political because these are not conducted in the manner of the *agōn* – debate and persuasion – but in the manner of war, i.e., cunning and deception (Arendt, 2005: 164). For the Greeks, the *agōn* was an integrating practice seated in the *polis*, while beyond the *polis* enemies were engaged with through wars of annihilation. Arendt explains that the Greeks 'became themselves' through struggle and war, but in the case of war, once battle had ceased, they retreated inside the walls of the city 'to be with themselves and their glory' (2005: 178).

For the Greeks, the founding law, or *nomos*, was applicable only to the space it constituted, enclosed, and delimited, i.e., the particular *polis*. Furthermore, the law was in effect pre-political, or at least, disconnected from political life. A lawgiver need not be a citizen, but could be commissioned, much like a sculptor or architect, 'to supply what the city required' (Arendt, 2005: 179). The consequence of this way of constituting and bounding the realm of politics was that it was spatially constricted. According to Arendt, though life in the *polis* was 'an intense and uninterrupted contest of all against all,' with citizens 'ceaselessly showing themselves to be the best,' it created an 'agonal spirit' that made alliances with rival states and city-states all but impossible (2005: 181). In short, the agonism that integrated the *polis* could not extend to a politics of interstate rivalry.

Following the thread of Homer's poem, Arendt suggests that the Romans 'were the twin people of the Greeks,' partly because they derived their origin from the same event: the Trojan War (2005: 173). Historical cousins perhaps, but for the Romans "politics grew not between citizens of equal rank within a city, but rather between alien and unequally matched peoples who first came together in battle" (2005: 178). Unlike the Greek *nomos*, the founding law of Rome – the Twelve Tables – "was not the work of one man, but rather a contract between two warring factions, the patricians and the plebes, that required

the approval of the entire populace, the *census omnium*" (2005: 179). In contrast to the insularity of Greek politics, Arendt explains that the original meaning of the Roman *lex* (law) is 'lasting tie,' which eventually came to mean 'contract,' so that laws (and treaties) tied human beings together, not coercively, but through mutual agreement. Roman law was enacted as an intrinsic part of political process, with the result that political struggle – including interstate rivalry – could give rise to "new political arenas" (2005: 178). Most importantly (Carthage being the exception), these were not wars of annihilation, because the Romans understood struggle as "the means by which they recognised both themselves and their opponents" (2005: 178).

For the Greeks, war brought an end to speech (and thus politics) by silencing the contest of words and deploying violence in their stead. For the Romans, war was a prelude to speech, which carried politics beyond the boundaries of the established state. There is a pragmatism to this, which anticipates discussion of Mouffe below, but we should first note, from Arendt, that the Roman agon should not be seen as an ethical enlargement of the political. The Roman way was to vanquish *and* spare an adversary, not out of compassion, but for the sake of expanding the reach of Rome.

There are three things of note to be distilled from the above discussion on the ancient *agōn*, i.e., three axes of contingency, which are constitutive of, and constituted by, an agonistic politics: how the space of politics is internally configured, how it is bounded against an outside, and how these dimensions of political order combine in modulating conflict, struggle, and violence. Together, these can be taken as the focus of contemporary agonism.

Staging the Contest

In a review article titled 'Political Theory and the Agony of Politics' (2007), Andrew Schaap opens with a very appropriate example of agonistic political thought: the contest between liberals and communitarians, which was to the fore of Anglo–American political theory during the 1980s. Schaap notes that the liberals are widely considered to have been the victors in that particular debate, but liberal political theory was itself transformed as a result of the encounter, which can be seen in how John Rawls' seminal, *A Theory of Justice* – which was very much the focus of communitarian critique – was reworked as a theory of *Political Liberalism* (1993). In the earlier work, Rawls used rational self-interest in place of a hypothetical social contract, building his theory around a figure of solitary introspection who was placed behind a 'veil of ignorance,' thus ensuring impartiality in the choice of principles that would 'define the appropriate distribution of the benefits and burdens of social cooperation.' In his *Political Liberalism*, Rawls' retains the original position, but it is now an "undistorted point of view from which fair *agreement* can be reached" (1993: 23, emphasis added), and here it is clear that the earlier figure of solitary introspection has entered into dialogue with others, and does so out of allegiance to a shared 'comprehensive doctrine' of values and beliefs. Furthermore, Rawls' defense of 'reasonable pluralism' insists that those who subscribe to this comprehensive doctrine be willing to engage in dialogue with others who do not, and in this way will endeavor to achieve an 'overlapping consensus' on matters of public import. This shift toward a distinctly dialogic liberalism coincides with developments in democratic theory, which pivot around the concept of 'deliberation,' which is the idea that disagreements can, and ought to be resolved through a process of public debate whereby participants reach collectively binding decisions, not through coercion and violence, but on the basis of what Jürgen Habermas calls the "force of the better argument" (1996). There are certain idealizations at work in the theory of deliberative democracy: that disagreements can be resolved through the public exchange of reasons, that participants are open to persuasion, and that each is willing to recognize the best argument as having validity for all. Habermas would add that such idealizations are not mere abstractions; that they can be reconstructed from how people actually communicate in their everyday lives, and that communication has an inbuilt *telos*, which is to reach mutual understanding and agreement, which together add up to his way of thinking about consensus. It is this ideal of 'consensus' – everything it assumes, implies and, perhaps most importantly, *insists* upon – which is perceived to be so troublesome by those who describe themselves as agonists.

Bonnie Honig (1993) places this dialogic/deliberative trend in political theory under the heading of 'virtue theory,' by which she means thinkers who equate politics with juridical, administrative, and regulative tasks geared to the objective of securing consensus and stabilizing intercommunal relations. For Honig (echoing Arendt), there is a misguided assumption shared by virtue theorists that politics, if done correctly, can be concluded by freeing us from conflict and instability. From an agonistic perspective, this is seen to 'close down the agon' by "duplicitously participating in its contests while pretending to rise above them" (Honig, 1993: 2). Similarly, Schaap insists that political theory must question "liberalism's continuing disavowal of its own political exclusions" (2007: 57). This is also what Honig refers to when she writes of the disruptive and disorderly 'remainders' of virtue theory, which in the world of actual politics carries implications for those perceived to be other. It is this abundance of being – the impossibility of creating order without also constituting remainders – that Honig has in mind when she sets *virtù* into play against virtue, and she does this by drawing on the work of Arendt and Nietzsche so as to "disrupt the closures of moral and political system" and "create new spaces of possibility" (1993: 4).

Abundance, remainders, exclusion, difference, and disruption – these are among the key ideas, which are brought into play against ideals of consensus, order, unity and stability, and together they gesture toward contest and struggle as the lifeblood of 'the political.' While contemporary agonists share a grounding in poststructuralism, they also exhibit important differences in how these ideas are deployed in the service of an agonistic politics, as can be seen by contrasting the expressive agonism of Connolly with the pragmatic agonism of Mouffe.

The Expressive Agon: Pluralization against Pluralism

There is a certain ambiguity in Arendt's discussion of the ancient agon. She is clearly endeared to the Greek *agora*, and

there are reasons to be wary of the Roman mode of conquest, yet there is a promise that emerges from the interweaving of these two ways of practicing an agonistic politics. For Arendt, 'the world' arises *between* people. Freedom and power cannot be the property of an individual, but can only exist among people in their plurality, in their living together, by their participating in political struggle, by 'showing themselves' to others through speech, and in this way coming to recognize both oneself and one's opponent as bearers of a freedom, which is granted to each other.

Some of the key coordinates of the expressive agon can be identified in this conception of political life: a vibrant public space where people voice their opinions and disagreements; where citizens come to see the 'many-sidedness' of things; and where, ultimately, they act in concert to produce earthly 'miracles' – meaning that when people interact politically, something is born from their intrinsic differences that could not have been foreseen at the outset. For Arendt, this is how politics must be understood. It is also the kind of freedom Arendt has in mind when she uses words like 'action' and 'power,' which meet in the idea of acting in 'concert.' And yet her account of the ancient agon offers a compelling example of how concerted action can lead to an insular political realm, which is constituted through exclusion. Connolly's version of the expressive agon can be seem to radicalize the Arendtian conception of politics by challenging what is, arguably, its core value: pluralism as a way of constituting and bounding the political.

According to Connolly, 'conventional' pluralism claims to celebrate diversity, but this is a diversity that exists only within 'settled contexts of conflict and collective action,' so that the question of diversity is resolved, and the scope of diversity itself bounded, by the territorial state, by the notion of a normal individual, and by monotheistic and monosecular conceptions of morality. As a result of such constrictions, the 'pluralist imagination' remains "too stingy, cramped, and defensive for the world we now inhabit" (1995: xii–xiii). For Connolly, plural*ism* must be continually unbound, so that the space of political struggle becomes an unending process of plural*ization*. This argument, which has been formulated through a sustained critical engagement with conventional pluralism, pivots around the notion of contestability, which is the focus of Connolly's work on *The Terms of Political Discourse* (1993a). Building on W.B. Gallie's essay on 'essentially contested concepts,' Connolly effects a subtle revision to Gallie's thesis by suggesting that the terms of political discourse may well be contest*able*, but whether they are contested or not has much to do with the 'politics of discourse.' The argument is that political discourse is saturated with a contingency that runs like a fault line through shared concepts and judgments, but that the contestability of political discourse is itself contingent. An attempt to contest the settled meaning of 'authority,' for example, might fall on deaf or hostile ears, negated by those who deploy a universalist discourse – whether God's will, or reason, or nature – to protect what Connolly calls 'provincial practices,' i.e., practices that anchor a particular form of life (1993a: 226). Contestation can be blocked by those who see themselves as having 'transcended the politics of discourse,' and while this might take the form of fundamentalist beliefs, it can also take the form of reification in the academic world of political theory and political science.

If, as Connolly argues, all practices are provincial, and if the terms of political discourse are contestable, then nothing is fundamental, and politics goes all the way down to being itself. Yet even here, at the threshold between politics and the political, Connolly refuses to be bound by the *logos* of ontology, which presupposes something fundamental, whether a logic or design, which can be encapsulated in a stable and complete representation of reality or existence. For Connolly, and whether we look to Marx or Hegel or some other variant, modern ontology "projects the possibility of drawing all otherness into the whole it endorses," so that "any otherness which persists will be interpreted as irrationality, irresponsibility, incapacity or perversity. It can never be acknowledged as that which is produced by the order it unsettles" (1993b: 132). Rejecting the *logos* but acknowledging that political interpretation necessarily 'invokes a set of fundaments,' Connolly offers us 'ontopolitical interpretation' as a means of staging agonistic political thought (1995: 1). Derived from Nietzsche, this is a concern with the abundance of being, or rather with the abundance that overflows settled conceptions of being. In ontopolitical terms, one of the tasks involved in critical thinking is to strip away the self-evidence of judgments that claim political or procedural neutrality, so that otherness is not so easily subdued by declaring it to be the manifestation of vice, abnormality, or madness. Connolly thus seeks to draw us into an ontopolitics of struggle and contestation where the paradox of identity/difference is not encountered as a puzzle to be solved, but as the basis of practicing 'agonistic respect' and cultivating an 'ethics of critical responsiveness' (1995). Connolly describes critical responsiveness as "an indispensible lubricant of political pluralization" (1995: xvii). As a mode of engaging with others who are perceived to be different, it does not attempt assimilation, but instead commences from an awareness and acknowledgment of identity and difference as a mutually constitutive relation, i.e., that identity is possible only because of difference, while difference is in turn dependent on identity. Furthermore, a relational field of identities is never more than provisionally stable, because difference can disturb the field in ways that transform its constituent elements. When it comes to the more practical question of practicing an ethics of critical responsiveness, Connolly explains that this is about turning a disturbance of what one is into a critical responsiveness to what one is not, so that the experience of disturbance is both intrasubjective and intersubjective (1995: xviii; Wenman, 2008: 202–206). Further to this, the willingness to engage with others through agonistic respect, whether this is extended to a person or a creed, must be 'cultivated,' which is the labor or effort involved in pluralizing the pluralist imagination. The overall objective then is to ensure that the boundaries of ontopolitical enclosures and identities retain a porosity that keeps them in a state of receptiveness and openness to encounters with difference.

The Pragmatic Agon: Agonism against Antagonism

In contrast to the expressive agon, Mouffe's theory of agonistic democracy has been described as 'pragmatic' (Schaap, 2009: 1). Mouffe does not build a normative theory that pivots around an absent presence: an immanent counterfactual such as

Habermas' ideal speech, or an ethical step beyond what currently exists, as in Connolly's pluralization. Mouffe does not imagine and celebrate a time-to-come, which will be hospitable to difference. The pragmatic agon is instead a response to what, for Mouffe, is an inescapable fact of human coexistence: there can be no *demos*, no *polis*, no political unity of any kind without exclusion. According to Mouffe, the paradox of identity/difference takes the form of a hegemony, which is constituted by an 'outside': an excluded surplus or excess, which can never be fully incorporated, and which is both the product of past antagonisms and the source of further (potential) conflicts. In short, struggle and conflict are ineradicable features of political life.

For Mouffe, democratic political thought exhibits a pervasive blindness – a naïve or blinkered understanding of human sociality, which is founded on what she describes as an 'optimistic anthropology': the idea that people are 'moved by empathy and reciprocity,' which leads on to the misguided assumption that rational deliberation can take us beyond enmity and violence. The mistake, argues Mouffe, is to overlook the salience and centrality of 'passions' in political life, and thus to miss the ways in which desire and fantasy – as affective dimensions of collective identifications – can be mobilized (2005: 5–6). For Mouffe, such passionate attachment is not, as liberals and deliberative democrats would have it – a threat to democracy. Instead, it is the inescapable 'how' of politics, and unless this is recognized, then democracy can only sow the seeds of its own destruction, because agonistic struggle will be repressed only to reemerge as violence.

There is an obvious affinity here with Arendt's distinction between politics/power and violence. Mouffe also seems to share Arendt's concern that equating freedom with a post-political vision of harmonious existence – whether among citizens or between nations and states – is to misunderstand the nature of the political. The comparison to Arendt must not be overstated, however, for Mouffe does not model her understanding of politics on the *agora*; it is instead the strategic politics of the Roman way which offers a more suitable analogue. According to Mouffe, antagonism *is* 'the political,' so that the task for democratic theory, as much as for a democratic politics, is to modulate antagonism in such a way that it takes the form of struggle among adversaries rather than a war of annihilation between enemies. If this is what, in Arendt's account of the ancient agon, distinguishes the Romans from the Greeks, it is also what distinguishes the agonism of Mouffe from that of Connolly: the pragmatic agon is not configured as an *ethics* but as a *politics* (Mouffe, 2000: 107n). It might also be noted that while Mouffe seems to converge with Connolly in her commitment to what she calls 'agonistic pluralism,' her way of theorizing this is entirely consistent with her social ontology (antagonism), which is derived from her engagement with Carl Schmitt. Given Schmitt's well-known "compromise with Nazism" (Mouffe, 2005: 4–5), Mouffe is aware that she is making a controversial move, but it is one that entails using Schmitt *against* Schmitt (2000: chap. 2). The key insight derived from Schmitt is his conception of 'the political,' which, he says, "must … rest on its own ultimate distinctions," and what sets this apart from other dimensions of human existence – the moral, the aesthetic, and the economic – is the distinction between *friend* and *enemy*. For Schmitt, it is this distinction that articulates all political relations of "union and separation, association and dissociation" (Schmitt, 1996[1932]: 26–27). For Mouffe, this essential relation of enmity, which is framed in such absolute terms by Schmitt, is the "necessary starting point for envisioning the aims of democratic politics" (2005: 13–14). But what Mouffe proposes, against Schmitt, is to configure the friend–enemy relation in such a way that struggle can accommodate "the pluralism, which is constitutive of modern democracy" (2005: 14). Schmitt insisted on a fundamental opposition between liberal morality and the democratic ideal: between the liberal conception of equal moral worth and democratic equality, which is based on a *political* distinction between those who can be counted among 'us' and those who do not belong. For Schmitt, the relationship between liberalism and democracy is one of mutual negation; they cannot coexist. Moving against the grain of this diagnosis of political modernity, Mouffe argues that we should understand the relationship between the liberal and democratic political traditions as a contingent historical articulation – a fortuitous accident, which has resulted in a paradox. But the 'democratic paradox' (2000) is not a puzzle to be solved so much as a way of staging agonistic political strategies. In short, if opponents meet as adversaries rather than enemies, then the democratic contest will prevail. This is the distinction that Mouffe makes between 'antagonism' and 'agonism': an agonistic democracy is one where "confrontation is kept open, power relations are always being put into question, and no victory can be final" (2000: 15).

For Mouffe, a democratic politics is more than the established laws and institutions of the democratic state. It is also the ideas and meanings that shape the practice of politics, which in the case of liberal democracy, have been forged from what she describes as distinct conceptual 'grammars.' Competing ways of interpreting ideals such as 'liberty,' 'solidarity,' 'equality,' 'rights,' and 'justice' (Connolly would say the essential contestability of such concepts) means that, for example, in a situation where a politics of 'we the people' threatens to overwhelm difference and diversity, then it is possible to use liberal discourse as a way of staging a counterhegemonic strategy. Moving in the opposite direction, in a neo-liberalized world, democratic ideals of solidarity can be invoked to struggle for distributive justice, and here there is an interesting overlap with Kalyvas' democratic narcissus: the way in which the ancient agon was stretched between desire for personal glory and serving the *polis*. There are echoes of this in how Mouffe interprets the pitfalls and possibilities of present day politics: a tension or paradox between individualized competitions to separate the best from the rest and agonistic contests geared toward the public good. While the former are likely to give rise to zero-sum relations of power, the latter dovetail with the positive-sum contests that Arendt had in mind when she equated politics with concerted power.

Concluding Reflections

Writing from within the frame of agonism, Andrew Schaap has suggested that "theorists of agonistic politics today are presented with a choice between Arendt and Schmitt" (2007: 60).

One might add that such a choice would resemble a decision as to whether politics should be modeled on the agonism of the ancient Greeks or ancient Rome. But to accept the inevitability of such a choice is in itself a way of closing down the agon. Perhaps it is not a choice between the expressive vs the pragmatic, so much as a question of strategy: of how to enact these agonistic games through specific engagements, encounters, and problematizations. The question of how to stage such strategies surely cannot be settled in advance, i.e., before struggle has commenced, and thus before the parameters and contours of particular struggles have entered into the realm of experience. But whatever form struggle takes, it is perhaps worth remembering, from the ancients, that the practice of agonism is shaped by the ways in which the space of politics is internally configured and bounded against an outside. It is the political context in question, which is likely to determine the likelihood of either an ethics of critical engagement or a counter-hegemonic political strategy succeeding, i.e., in accordance with the agonistic understanding of pluralism.

Agraphia (Acquired Dysgraphia)

Claudio Luzzatti, University of Milano-Bicocca, Milano, Italy

Abstract

Over the last 150 years, neuroscientists and cognitive neuropsychologists have focused their attention on the acquired writing impairments that may follow a left-hemisphere brain damage (*agraphia*, or *acquired dysgraphia*). During this period, the most effective method to gain understanding of the mental processing of written language and its neurobiological foundation has been the observation of patients suffering from acquired writing deficits. Recently, a massive quantity of additional information regarding the neural writing substrate has been obtained from neuroimaging data. The present article also describes the different types of writing deficits that occur after brain damage and clarifies the principles used in their diagnosis.

Agraphia is an acquired writing impairment generally caused by left-hemisphere brain damage in individuals with normal premorbid literacy acquisition. The term was coined in 1869 by John William Ogle (1824–1905). As this article will describe acquired writing impairments caused by focal brain damage, a preliminary terminological clarification is helpful. The classical neurological authors of the nineteenth and twentieth centuries used the term *agraphia* to denote acquired, mostly isolated, spelling impairments, whereas the term *dysgraphia* was adopted to denote the developmental deficits involving the acquisition of writing abilities. However, the cognitive neuropsychologists of the second half of the twentieth century used the term *dysgraphia* to denote any spelling and writing impairment, irrespective of whether it was acquired or had a developmental origin. In line with this usage, for the purposes of this article the term *agraphia* will only be employed when referring to the classical clinical case descriptions of the nineteenth and early twentieth centuries, while the term *dysgraphia* will be used to describe all types of spelling and writing disorders, consistently with the contemporary cognitive neurolinguistic terminology.

Writing deficits are mostly associated with aphasia; in other words, acquired language impairments caused by left-hemisphere brain damage usually involve all linguistic units (i.e., the phonological, lexical, and morpho-syntactic abilities) and modalities (production and comprehension; oral and written language). Consequently, most aphasic patients suffer from proportionate damage also involving written language (acquired *reading and writing disorders*). Less frequently, focal brain damage may involve almost exclusively the processing of written language, and of writing in particular, which may depend on a spelling deficit, i.e., impaired orthographic processing or be specific to the retrieval of grapho-motor information, i.e., in handwriting only (*pure motor agraphia* and *dyspraxic agraphia*).

General Premises: Oral and Written Language

Written language differs quite radically from oral language, particularly, as far as the mechanisms underlying its acquisition are concerned, both from a philogenetical and onthogenetical point of view. The acquisition of oral language is genetically predetermined and automatic, i.e., a child acquires his/her mother tongue without any effort in a relatively fixed critical period of his/her development; the acquisition of written language, on the contrary, is effortful, and requires specific training. Moreover it cannot be considered as being genetically based, since its use was only introduced approximately 6000 years ago, a very short period of time in terms of natural evolution processes, and even in the Western hemisphere the use of the written language has only become widespread during the last few generations. Furthermore, a child born into an environment where historically there has never been any exposure to a written language acquires this competency with the same degree of skill and effort as a child born into a society where it has been present. This would indicate that written language does not have an independent genetic foundation, i.e., a foundation based on specific and innate neural basis.

Acquired Impairments of Written Language

Written Language Deficits in Classical Aphasiology

Several functional and neuroanatomical models of written-language processing were proposed by the classical neuropsychologists of the nineteenth century, mostly based on clinical observation of neuropsychological patients and on the assumption of lexical stores containing input and output word representations (e.g., Lichtheim, 1885; Charcot, 1883; see **Figures 1 and 2**). There were two main issues with these models, the first being whether written-word processing is dependent or independent from oral processing and the second regarding the mutual independence of the written input lexical store from the output lexical store.

In his seminal work on the neural basis of language, the Austrian physiologist Siegmund Exner (1881) (see **Figure 3**) identified a left-hemisphere area in the middle frontal gyrus (just above Broca's area and anterior to the primary motor control area of the hand), which he found to be critically involved in several patients suffering acquired writing impairments. Based on his anatomo-clinical correlative study, he concluded that this frontal area would play a specific role in regulating written expression. The French neurologist Albert

Ludwig Lichtheim, 1845–1928

Figure 1 Ludwig Lichtheim and his diagram applied to the processing of written language. A = center of the auditory images of words; B = center of the motor images of words; C = conceptual representation of objects; a = auditory analysis; b = speech motor programs; O = center of visual engrams (word reading); E = center of motor engrams of the hand (handwriting). Modified from Lichtheim, L., 1885. On aphasia. Brain 7, 433–484.

Pitres (1884) found a lesion in the same area to be the cause of pure motor agraphia with a relatively spared ability to spell out words. On the strength of this observation, he suggested that the motor memory of written letters and words is fully independent of the visual memory for letter shapes and letter combinations and the auditory memory of word sounds. However, on the basis of his observation of two patients, one suffering from isolated reading impairment (*pure alexia*, or *word blindness*) and one with reading and writing deficits (*alexia with agraphia*) but no oral production and comprehension deficit, Joseph-Jules Dejerine (1892) assumed a single store of written-word knowledge in the *left angular gyrus*, which must be accessed both in reading and writing (see Figure 4).

Dejerine's model of written language and Exner's writing center continued to be the major functional and neuroanatomical references for the neural foundations of written language processing, and of its impairment after brain damage, until the second half of the twentieth century.

The Cognitive Neuropsychological Approach to Written Language and Its Impairments

The classical functional and neuroanatomical models of language described so far were not able to account for certain

critical phenomena occurring in patients suffering from acquired reading and writing deficits such as semantic errors (*semantic paralexia* and *semantic paragraphia*), *imageability* effects (concrete words may be read or spelled better than abstract words), or *grammatical class* effects (nouns may be read or spelled more accurately than verbs, and the latter better than function words). Furthermore, different degrees of impairment were found in certain patients when processing words with differing orthographic aspects, such as regular words, irregular words (e.g., YACHT, /jɒt/ or COLONEL, /cornel/) or when processing *nonwords* (plausible phonological or orthographic

strings with no meaning like DOUGE). In fact, literate individuals are able to read or spell words with irregular orthography as well as nonwords, but this ability may be selectively disrupted after brain damage, with the result that disproportionate deficits for either irregular words or nonwords, either in reading or in spelling may ensue. This suggests that in literately proficient adults reading and spelling proceed along two parallel routes: a lexical route for processing regular and irregular words whose orthography had already been acquired, and a subword-level routine, which may be employed for processing both regular word and nonwords.

Not all languages that employ an alphabetic script system have the same degree of regularity; for instance, French and English have a relatively opaque transcription system, i.e., the pronunciation and orthography rules regulating these languages have a vast number of exceptions. In English, for example, the orthographic string EA may be read as /i:/ in VEAL, as /ε/ in HEAD, as /Λ/ in HEART, or as /ei/ in STEAK, and the diphthong /ei/ may be spelled as AI in BRAIN or A + consonant + E in FRAME. In other languages, like Italian or Spanish, exceptions are very few, and most words can be spelled and read aloud along both the sublexical and the lexical route.

Processing Models of Writing and Acquired Dysgraphia/Agraphia

Thus a model to account for the acquired spelling ability of a literate adult has to include two independent processing routes: the lexical and the sublexical procedure (see Figure 5).

The *sublexical route* permits the transcription of strings of sounds into the corresponding letter strings. It consists of a set of four sequential processing units: first of all the auditory stimulus is analyzed (*visual analysis*), after which the perceived phonetic string passes through an *auditory-to-phonological*

conversion process, by which it is segmented and sequenced into its corresponding phonemic string; the single phonemes are then stocked temporarily in the *phonological buffer*, a working memory store that can transmit them serially to the *phonological-to-orthographic conversion* unit; graphemic representations are then arranged serially in the *graphemic buffer*, a short term memory store in which the orthographic string can

Figure 5 Dual-route model of spelling and writing: lexical and subword-level routes. Modified from Patterson, K.E., 1986. Lexical but nonsemantic spelling. Cognitive Neuropsychology 3, 341–367.

be produced for use by one of the three major vehicles for the final output, i.e., handwriting, typing on a keyboard, or the serial retrieval of letter names (oral spelling). The sublexical route is used for writing acquired regular words whose orthography had been learned in the past (or not), and nonlexical phonological strings (nonwords). Irregular words cannot be spelled correctly by this route; in fact, when it is used regularization errors inevitably occur, i.e., substitution of the correct orthographic sequence with a phonologically plausible orthographic string.

Spelling along the *lexical route* is based on three lexical and semantic stores, i.e., the phonological input, the conceptual, and the orthographic output representations of words that have already been learned. After a preliminary auditory analysis, the known word is recognized in the *phonological input lexicon* through a mapping process by which it is matched with the corresponding stored phonological representation. This, in turn, is matched with the corresponding conceptual knowledge stored in the *cognitive system* (or *semantic system*) and activates the corresponding orthographic representation stored in the *orthographic output lexicon*, which contains the orthographic information regarding words whose correct orthography has been previously learned. The lexical route permits the spelling of regular words and is the only procedure available for spelling irregular words, but it cannot be used for spelling nonwords and words whose orthography has not been previously acquired.

Central and Peripheral Dysgraphias

Cognitive psychologists classify acquired spelling impairments, distinguishing between central and peripheral dysgraphias (see Figure 6). The central forms are the result of damage to either spelling routes and to the underlying functional components (*phonological*, *surface*, and *deep dysgraphia*). Peripheral forms, on the contrary, are caused by damage located below the graphemic buffer, and include callosal agraphia *(apraxic agraphia)*, *left-hand agraphia*, and *allographic dysgraphia*.

Central Dysgraphias

The dual-route spelling model predicts two independent forms of dysgraphia. Damage to the *phoneme-to-grapheme conversion* route results in a spelling disorder that is usually called *phonological dysgraphia*. Patients suffering this impairment are unable to spell nonwords, while they can access the correct orthography of regular and irregular words effortlessly.

Damage to the *lexical route* results in a spelling disorder that is usually known as *surface dysgraphia* (or *lexical dysgraphia)*. Patients suffering from this type of dysgraphia regularize the spelling of irregular words (phonologically plausible errors), i.e., they spell COUGH as KOFF, GENUINE as JENUWEN and CASTLE as CASSELL. Errors of this type clearly indicate that the patient is spelling along the sublexical procedure. However the spelling of regular words and nonwords is relatively preserved (see Figure 6).

Deep dysgraphia. The characteristics of this spelling deficit are very similar to those of phonological dysgraphia. Besides the deficit in spelling nonwords, deep dysgraphic patients also generate *semantic substitutions* (e.g., DOG for HOUND or TREE for FOREST), *morphological errors* (SING for SINGING), lexical effects such as *word frequency* (lower accuracy for low frequency words), *grammatical class* (nouns are spelled better than verbs, and verbs are spelled better than function words), and *imageability* effects (concrete words are spelled better than abstract words). Semantic substitutions are usually explained as the consequence of an instability of the semantic system causing incongruent activation of the orthographic output representation of words that are semantically related to a target word, in the absence of a direct lexical or subword-level mediated output control.

Graphemic buffer dysgraphia. When a spelling disorder originates at the graphemic buffer level a length effect may be

Figure 6 Major types of dysgraphia after acquired brain damage caused by disproportionate damage to either route: functional damages causing phonological and surface dysgraphia. Modified from Patterson, K.E., 1986. Lexical but nonsemantic spelling. Cognitive Neuropsychology 3, 341–367.

observed and graphemic transpositions, omissions, and substitutions predominate among error types. The syllabic structure of the target words is usually preserved, with conservation of the consonant-vowel structure (Glasspool and Houghton, 2005) so that vowels usually substitute other vowels, consonants other consonants, consonant clusters other consonant clusters. The impairment also involves, in parallel, the spelling of words as well as nonwords. These phenomena indicate that transpositions and substitutions originate at a later phase of the spelling process, i.e., at the point when the orthographic syllabic structure has already been encoded.

Peripheral Dysgraphias

These types of acquired dysgraphia originate at various processing levels located below the graphemic buffer. In this phase of the writing performance, the writing process consists of the translation of allographic symbols – the representations of the various letter shapes (e.g., A, a, *a*) – into the corresponding writing movements.

Apraxic agraphia is a writing deficit caused by the inability either to retrieve the letter shapes from a visual or motor memory store, or to produce their graphic motor pattern. This impairment does not result from primary limb or constructional apraxia, since these disorders are not necessarily associated with apraxic agraphia and, vice versa, apraxic agraphia may develop in the absence of either limb or constructional apraxia. Since the impairment consists in an inability to produce the graphic form of letters, and not in a loss of orthographic knowledge, writing on a keyboard and oral spelling are usually unimpaired.

Callosal agraphia (left-hand agraphia) is further type of impairment that affects the writing ability of the left hand only: this form of agraphia is usually caused by damage to the anteromedial tract of the corpus callosum, which results in the left-hand motor centers (right hemisphere) being disconnected from the orthographic knowledge located in the left hemisphere.

Another writing deficit is *allographic dysgraphia*, so-called because it impairs the various allographic handwriting codes (*allographs*): capital letters/italics; uppercase/lowercase. As in the case of the other peripheral dysgraphias, the allographic writing disorder differs from central dysgraphia in that it does not affect oral spelling and writing on a keyboard and handwriting is relatively fluent and letters are well formed. Finally, certain patients are unable to distinguish between capital letters and italics, uppercase and lowercase allographs, and mix different formats in the same text (e.g., d*r*OmE*da*Ry).

Principles in the Assessment of Writing Impairments

Acquired writing impairments are assessed in order to identify the processing units damaged by a cerebral lesion; an assessment is an essential prerequisite for the preparation of a cognitively oriented treatment program (Luzzatti et al., 2000).

In line with the principles outlined by the contemporary cognitive neurorehabilitation standards, a writing assessment (*writing from dictation*) has to contain lexical (regular words, irregular words) and nonlexical (nonwords) stimuli (e.g., Luzzatti et al., 1998).

The integrity of the lexical route can be assessed through performance on irregular words, that of the sublexical route by performance on nonwords. Target stimuli must be selected from different grammatical classes (nouns, verbs, function words) and must vary in length, concreteness, and word frequency. The integrity of the orthographic output lexicon should also be assessed with a written naming task (usually picture naming). When diagnosing peripheral dysgraphia, it is useful to compare the performance on *handwriting* with that on *oral spelling*. With regard to the English language, the Psycholinguistic Assessment of Language Processing in Aphasia assessment battery (PALPA: Kay et al., 1992) responds

appropriately to most of these principles, assessing the spelling of concrete and abstract words, high- and low-frequency words, content and function words, nonwords, as well as written naming.

Neuroanatomy of Writing

As stated in the introductory remarks, there are no grounds for assuming that the processing of the written language is based on a genetically independent neurofunctional circuitry. Consistently with this assumption, studies that have tried to define the neural correlates of the dual-route models of reading and writing have not obtained univocal results.

Anatomo-clinical correlative studies indicate an association of phonological dysgraphia with damage to the supramarginal gyrus and/or the insula, sparing the angular gyrus, while surface dysgraphia with damage to the left angular gyrus (e.g., Rapcsak and Beeson, 2002; Roeltgen and Heilman, 1984), thus supporting Dejerine's hypothesis concerning the importance of this area both for reading and writing (and in particular along the lexical route). However, other anatomo-clinical correlative studies (Rapcsak and Beeson, 2004) and certain functional neuroimaging studies (Beeson et al., 2003) have indicated that the fusiform gyrus and the inferior temporal cortex may have a relevant role as possible stores of lexical orthographic knowledge that need to be accessed both in word reading and in spelling. Furthermore, neuroimaging data indicate a functional overlap between the neural circuits involved in spelling and those involved in spoken language, and between the functional circuits underlying lexical and subword-level spelling performances (e.g., Norton et al., 2007).

Agrarian Political Economy

Henry Bernstein, University of London, London, UK; and China Agricultural University, Beijing, China

Abstract

Agrarian political economy in its current sense originated in the 1960s, although it has longer intellectual antecedents. It can be defined as investigation of "the social relations and dynamics of production and reproduction, property and power in agrarian formations and their processes of change, both historical and contemporary". Its substantive research and debates have centered on the class dynamics and gender dynamics of (1) precapitalist agrarian formations in different parts of the world; (2) paths of agrarian change in transitions to capitalism in the now-developed countries; (3) agrarian change in experiences of colonialism; and (4) subsequent processes of change in the moment of (state-led) 'developmentalism' following political independence and the current moment of market-driven ('neoliberal') globalization.

Agrarian political economy in its contemporary usage originated in the 1960s. It is defined by *The Journal of Agrarian Change* as investigation of "the social relations and dynamics of production and reproduction, property and power in agrarian formations and their processes of change, both historical and contemporary".

Its antecedents as a field of study are the classical political economy of eighteenth century England, Scotland, and France, centered on issues of agrarian capitalism according to David McNally's potent 'reinterpretation' (1983), and the scattered writings of Marx and Engels on capitalist agriculture. Of particular note among the latter is Marx's account of 'primitive accumulation': the process by which the conditions of capitalism were established first in the English countryside through the dispossession of peasants (to become proletarians or wage workers), the conversion of land to a commodity, and of farming to market-oriented production, hence investment to make profit (Marx, 1976). Other intellectual antecedents available to 'rediscovery' by agrarian political economy also included the great debates from the 1880s among "Russia's leading economists, statisticians, sociologists, and agricultural experts…[who] provided the richest analytical literature we have on the peasant economy of any country in the period since the Industrial Revolution" (Thorner, 1966: xii), not least Lenin's *Development of Capitalism in Russia* (1964, first published 1899) and Chayanov's *The Theory of Peasant Economy* (1966, first published 1925); Karl Kautsky's *The Agrarian Question* (1988, the first full English translation of a book published in 1899); as well as the work of earlier radical intellectuals from Latin America and colonial Asia and Africa.

Agrarian political economy quickly became a lively, diverse, and contentious field of study and debate across a wide terrain: from the functioning of household farm production in different places at different times (Bernstein, 2010) thru the place of agriculture in different paths of (national) economic development in modern history (Friedmann and McMichael, 1989; Byres, 1991, 1996) to its place in the formation and development of a capitalist world economy (Wallerstein, 1974; Friedmann, 1978, 1982; Schwartz, 2000). The diversity of the field is, in various parts, an effect of (1) its interdisciplinary character, encompassing important contributions from Anthropology, Economics, Geography, History, Law, Political Science, and Sociology; (2) the applications, and clashes, of different paradigms within and across such disciplines; (3) the wide range of its historical and contemporary concerns; and (4) differences between scholars committed to the methods of materialist (Marxist) political economy. Because of such diversity of objects of study and approaches, historical periods, and interpretations, it is possible only to select and illustrate briefly some of the areas encompassed by agrarian political economy in its dynamic recent career, with this review limited to the anglophone academy.

A Founding Moment

One major stimulus, and an enduring preoccupation, was the effort to understand better the problems and prospects of economic and social development of poorer countries (only recently independent of colonial rule in most of Asia and Africa), in which "the peasant is a very essential factor of the population, production and political power" as Engels (1970: 457) had remarked of France and Germany some 80 years earlier.

A second and connected factor, in addition to its intrinsic interest, was the commitment to exploring and testing the possible contributions to such understanding of knowledge of (1) precapitalist agrarian formations in different parts of the world; (2) paths of agrarian change in transitions to capitalism in the now-developed countries; and (3) the dynamics of agrarian change in Latin American, Asian, and African experiences of colonialism, and their legacies for subsequent processes of development and underdevelopment (Bernstein and Byres, 2001).

Key works in the 'founding moment' were Eric Wolf's textbook on *Peasants* (1966) and his *Peasant Wars of the Twentieth Century* (1969); Barrington Moore Jr.'s *The Social Origins of Dictatorship and Democracy: Lord and Peasant in the Making of the Modern World* (1967); the first English translation of a major work by the great Russian scholar A.V. Chayanov, *The Theory of Peasant Economy* (1966); major historical studies of the Russian peasantry before and following the Bolshevik revolution by

Lewin (1968) and Shanin (1973); and the first of a series of influential studies by James C. Scott, *The Moral Economy of the Peasant* (1976). Wolf, Barrington Moore Jr., and Scott pursued new questions beyond the mostly European focus of 'classic' Marxism. Wolf's work was informed by his studies of Mexico, and Latin America and the Caribbean more widely, and his book on peasant wars comprised case studies of Mexico, Russia, China, Vietnam, Algeria, and Cuba. Barrington Moore's great comparative study of the centrality of agrarian class struggle to different paths of state formation in the modern world encompassed the 'classic' European instances of England and France, plus the USA, and Japan, China, and India (further informed by his interest in the historical trajectories of Prussia/Germany and Russia/USSR). Scott's main region of fieldwork is Southeast Asia.

Wolf (1966) and Shanin (1973) were especially relevant to consideration of peasant social structure, Barrington Moore and Scott to peasants and politics (as was Wolf, 1969; Shanin, 1973), and Chayanov (1966) to the nature and logic of peasant agriculture. The distinctiveness of Chayanov's model consisted in its combination of a claim for peasant economy as a general (and generic) 'type' of economy, and staking that claim on a marginalist analysis of the behavior of the peasant household as a unitary farming enterprise, especially in terms of the 'demographic cycle' of generational reproduction.

What was missing from Chayanov's model of peasant economy, as from other forerunners of contemporary agrarian political economy, was any consideration of gender relations within farming households, and indeed how gender relations affect who owns what (notably but not exclusively land), who does what (divisions of labor within household farming), who gets what (divisions of the fruits of labor), what they do with it (various reproduction costs), and who decides such matters. These kinds of issues, and the significance of very different social forms of rural households and of the different ways in which they manage production and reproduction, were impressed on the attention of agrarian political economy by the impact of new feminist scholarship in the social sciences (Young et al., 1981; Kandiyoti, 1985; Agarwal, 1994; Razavi, 2003). 'Gender-blind' notions of the farm household, whether as a unit of 'utility maximization' as in Chayanov or established in other theoretical traditions (for example, petty commodity production in Marx and Lenin), were no longer tenable, and the gender as well as class differentiation of farmers (and the interconnections of gender and class) was gradually incorporated in agrarian political economy, if unevenly so.

Important institutional expressions of the field of agrarian political economy as it emerged and consolidated include, notably, the 'Peasants Seminar' of the University of London convened by Terence J. Byres from 1972 to 1989, which led to the founding of the *Journal of Peasant Studies* in 1973 (Byres, 2001); the *Agrarian Studies Program* at Yale University established by James C. Scott in 1991; the founding of the *Journal of Agrarian Change* in 2001; more recently the *Initiatives in Critical Agrarian Studies* program at the Institute of Social Studies in The Hague, the Netherlands, established by Saturnino M. Borras Jr.; and the new journals *Review of Agrarian Studies* (from 2011) and *Agrarian South; Journal of Political Economy* (from 2012) based in India.

Historical Explorations

Precapitalist Agrarian Formations

This can only be illustrated briefly from a vast literature on agrarian civilizations before capitalism. Whether the characteristics of European feudalism were found in other regions of the world, and especially South Asia, was addressed in a collection edited by Byres and Mukhia (1985), and also impacted on debate of 'tributary modes of production' to characterize the great agrarian civilizations of the East (Haldon, 1993; Banaji, 2010). Bray (1986) argued that the historic rice economies of East and Southeast Asia suggest a model of development of contemporary relevance very different from standard views of 'modern' agriculture derived from Western Europe and North America, and centered on highly capitalized farming. Debate of a transition to feudalism in Europe has been further stimulated by the *magnum opus* of Wickham (2005), subject to critique by Banaji (2010), also the author of a major materialist study of agrarian change in late antiquity (Banaji, 2001).

Part of the interest of such works of scholarship is how they employ key concepts and methods of political economy concerning class analysis and state formation to investigate agrarian pasts, and also how their findings bear on the conditions in which agrarian capitalism emerged and developed – or failed to do so.

Transitions to Capitalism

Schematically, there are two approaches in Marxist and *Marxisant* debate of the origin of capitalism (both of which can claim support from Marx's writings). One locates it in the formation of a 'world system' from the fifteenth or sixteenth centuries. The other approach centers on the transition from feudalism to capitalism in Northwest Europe from the fourteenth century or so, with the search for the 'prime mover' in the transition revisited in a seminal essay by Brenner (1976; Aston and Philpin, 1985; Wood, 2002).

Brenner explained the initial emergence of capitalist farming as a specific and conjunctural outcome of class struggle between (feudal) lords and peasants in England in contrast to France and Germany. Once established, however, capitalist agriculture – with its competitive compulsions of 'market dependence' – both paved the way for England's subsequent 'first industrial revolution' in the late eighteenth century, and generated systemic effects elsewhere. For Brenner, only capitalism was able to generate "a process of self-sustaining economic development characterized by rising labor productivity in agriculture" that overcame two obstacles that had confronted all previous agrarian civilizations: the long-term tendency of population to outrun food supply and the inability of urban population, and nonagricultural labor, to grow beyond a highly limited proportion of total population (Brenner, 2001: 171–172). Brenner's theoretical approach continues both to inspire other historical studies (e.g., Post 2011, on the agrarian origins of US capitalism) and to draw trenchant criticism (e.g., Heller, 2011).

Colonial Experiences

The colonial projects of European countries, and their various places, timings, impulses, and forms – in Latin America, Asia,

and Africa from the late fifteenth to the twentieth centuries – involved controlling and (re)organizing the labor of the colonial subjects of agrarian societies (including importing African labor to supply slave plantations in the Americas, and indentured labor from South Asia and China for sugar plantations around the world). This required intervening in their institutions and practices of land allocation and use, sometimes destroying them, sometimes modifying them. In effect, the making of colonial economies involved the breaking and remaking of precolonial modes of peasant subsistence and of landlordism, rent, and tribute (in agrarian class societies), with various effects, unintended as well as intended.

This then is another vast and diverse historical terrain, explored by agrarian political economy with respect to the formation of new frontiers and forms of agriculture linked to different phases, and mutations, of world markets that supplied an industrializing Europe and North America. Key foci of such research are (1) forms of agricultural production in the colonies, and (2) the labor regimes they deployed. The former ranged in scale from the *haciendas* of temperate Latin America and the later settler farms of east, central, and southern Africa and 'industrial plantations' of South and Southeast Asia, and tropical Latin America, to reconfigurations of peasant farming to produce crops for export and for new domestic markets, and to supply labor to plantations, settler estates, and mines. In some cases, indigenous landed or other economically and politically powerful classes were able to establish profitable locations for themselves within the agrarian economies of colonial capitalism. Various labor regimes deployed, and sometimes combined, slavery, indentured, and other forms of coerced labor (as noted), especially seasonal wage labor of various degrees of 'freedom', and peasant labor both in household farming and employed in other kinds of enterprise, agricultural and nonagricultural like the regional migrant labor system of the South African mines (Bernstein, 2010).

Much debate in agrarian political economy concerns the precise social character and effects of farming shaped by colonial rule, especially how and how much it became capitalist, or represented various amalgams or 'articulations' of capitalist and precapitalist elements, involving a set of issues that are continuing concerns. These center on questions concerning the 'persistence' or 'survival' of peasant production and community, and whether this can be explained as beneficial to capitalism in some way (e.g., by lowering costs of both agricultural commodities and rural migrant labor) or by the resilience of peasant 'resistance' to market integration ('commodification') and the states that promoted it during colonialism and since.

Also much explored and debated is the question of class differentiation of the peasantry, tabled by Lenin (1964) in late nineteenth century Russia to extend, in effect, Marx's account of primitive accumulation in England and its peasant dispossession through enclosure of land as private property. Lenin's model proposed a tendency to dissolution of the peasantry into rich peasants engaged in expanded reproduction, accumulating land and capital to become emergent capitalist farmers; a diminishing number of middle peasants able to maintain simple reproduction; and poor peasants unable to reproduce themselves through their own farming, hence subject to proletarianization, the condition of 'free' landless workers in Marx's ironic use of the term, that is, 'freed' from access to means of production, hence free to work for wages or otherwise starve. Interestingly, a prominent (non-Marxist) scholar of colonialism, possibly influenced by agrarian political economy, argued that classes of rich peasants/emergent capitalist farmers were key to the political settlement of independence from colonial rule in much of Asia and Africa (Low, 1996).

Such issues carry forward to, and connect with, a third central theme: the effects of the extremely diverse forms of agrarian economy and producers created by varied colonial experiences for the ambitions and projects of 'national development' that marked the moment of political independence in Asia and Africa from the 1940s, with echoes of the significantly earlier period of independence in most of Latin America.

Development and Underdevelopment (1950s–70s)

The newly independent countries of Asia and Africa emerged from colonialism still largely agrarian societies but now committed to 'national development', as were most Latin American countries which were generally more industrialized. Modernizing agriculture was usually a central element of ideas about 'national development', if often subordinated to the desire for industrialization, seen as the principal economic basis of prosperity, modernity, and sovereignty. Giving it priority could mean substituting domestic grain production with cheap wheat imports from the USA (Friedmann, 1990), or 'postponing' agricultural modernization until the development of national industry could provide farmers with modern inputs, the dominant view in India for the first 20 years of independence before the 'Green Revolution' was launched.

During the peak period of 'developmentalism' – the pursuit of state-led development – from the 1950s to 1970s, a wide range of policy measures was adopted and applied by governments in the South to 'modernize' their agriculture. Agricultural policy was also used to try to resolve some of the social tensions and contradictions inherited from their colonial histories, no less in Latin America than in Asia and Africa. Thus, for example, land reforms, of very different kinds, were widespread in this period, as was government-imposed resettlement of rural populations (a familiar colonial practice), for example, in parts of Africa and Southeast Asia. The 'integrated rural development programs' of the 1970s, a comprehensive 'package' of education and health as well as economic services to the countryside, was promoted especially strongly by the World Bank and USAID (the US Agency for International Development), which some interpreted as their response to the success of a peasant-based and communist-led war of national liberation in Vietnam.

In this period, agricultural and more broadly rural development policies exhibited a lot of institutional variety and frequent 'paradigm shifts' or, more simply, changing fashions, as they do today. Despite their variety, policies and programs of modernization shared a core logic: promoting a more productive agriculture based in deepening commodity relations, whether through 'smallholder' development or larger scale farming, public and private. This was often pursued by governments in the South in 'partnership' with the

World Bank, bilateral aid donors, notably the USA, Britain, and France, and private agribusiness capital (national and international), all of which supplied designs for modernization.

'More productive' addresses the technical conditions of farming, through improved varieties and cultivation methods, and greater fertilizer use, together with 'soft' credit and technical advice to farmers (extension services). This was typically done on a crop basis, whether for export crops or food crops, most famously the Green Revolution from the 1960s and its high yielding variety (HYV) seeds of the 'big three' grains of wheat, rice, and corn (or maize, the original 'Green Revolution' crop in the USA). The 'package' combined HYV seeds with fertilizers, requiring substantial irrigation to produce larger harvests.

'Deepening commodity relations' involves greater integration of farmers in markets, in which they specialize in producing particular commodities for sale, as well as buying and using greater quantities of means of production ('modern' inputs) and means of consumption, which often include food.

It is difficult to generalize about the effects of agricultural modernization efforts during the moment of 'developmentalism', because of the variety of policy measures, of their technical and institutional 'packages' and of government capacities in delivering them; and the even greater variety of ecological conditions and types of farming to which they were applied. In fact, assessing the impact of policies – a sizable profession in itself – is always challenging, because agricultural 'performance' is affected by many other factors too, from weather to the effects of macroeconomic policies (for example, and notably, concerning exchange rates of currencies and interest rates), to the vagaries of markets and prices, locally and internationally.

Agrarian political economy engaged with, and contributed to, the analysis of agrarian change and its policy debates in the moment of 'developmentalism'. This partly drew from research on precapitalist agrarian formations in the South, paths of agrarian transition in now-developed countries, and colonial experiences of agrarian change and policies to promote it, all of which could be relevant to consideration whether capitalist agrarian transition was occurring and, if so, whether it was complete. Debate of agrarian change in the early decades of independence in Asia and Africa also highlighted a central tension between, on one side, those for whom modernization was a necessary component of agricultural growth, and its role in economic development more widely, requiring "peasant elimination" (Kitching, 2001) and, on the other side, "taking the part of peasants", in Williams' succinct expression (1976). This resonates a tradition of agrarian populism as long as the histories of capitalist agriculture and industrialization (Kitching, 1982). Agrarian populism declares the virtues of peasant or family farmers and identifies with their struggles against those who threaten their reproduction and well-being, from merchants and banks, capitalist landed property, agrarian capital and agribusiness, to projects of state-led 'national development' centered on industrialization, in all their capitalist, nationalist, and socialist variants, of which the Soviet collectivization of agriculture in the 1930s was the most potent landmark. Its modern versions draw on the legacy of Chayanov, himself a victim of Stalin's purges, whose vision of a future 'peasant utopia' combined household farming with cooperation to achieve economies of scale (Bernstein, 2009, and references therein).

This historic, indeed almost constitutive, tension in agrarian political economy is expressed in debates over, for example, the character and effects of land reforms that claim to redistribute 'land to the tiller' (e.g., de Janvry, 1981; Byres, 2004); the political obstacles to taxation of capitalist farmers and rich peasants to generate an accumulation fund for industrialization ('rural bias' or at least class bias; e.g., Mitra, 1977); and in opposition to the latter the argument of 'urban bias' as the principal barrier to stronger growth by smallholder farmers, hence overcoming rural poverty (Lipton, 1977). In turn this was criticized as a (neo)populist 'myth' by Byres (1979). These kinds of questions, and attendant disagreements, carried over, and have intensified if anything, as the moment of state-led 'developmentalism' gave way to the 'neoliberalism' of market-driven doctrines and practices of development in the context of globalization since the 1970s (see below).

Anti-Imperialism and Transitions to Socialism

Two of the defining global moments of the 1960s and early 1970s, the founding moment of contemporary agrarian political economy, were the Vietnamese war of national liberation (the stimulus to Wolf, 1969) and the 'Great Proletarian Cultural Revolution' and its aftermath in China.

Are there socialist alternatives to capitalist agriculture (including the contributions of agriculture to industrialization)? Curiously, while Russia from the last quarter of the nineteenth century to Stalin's sudden and dramatic collectivization of peasants remains a topic of intense interest in agrarian political economy, it has had little to say about the long period of Soviet agriculture from the 1930s to early 1990s. While there was once a keen interest in China's communes as an 'alternative' to both capitalism and Soviet state socialism, this withered with the dismantling of the communes from the 1970s. Most work on China since then has come from agricultural economics and anthropology rather than from agrarian political economy. Recent exceptions include characterizations of current agrarian change in China as "agrarian capitalism with Chinese characteristics" (Zhang and Donaldson, 2008) and "capitalization without proletarianization" (Huang et al., 2012).

Globalization and Development (1970s Onward)

This is another immensely wide-ranging area of research and both academic and public debate, which often contains impassioned positions that are far ahead of empirical knowledge and its judicious assessment. A list of highly topical issues concerning globalization and agrarian change includes:

1. trade liberalization, shifts in global trade patterns of agricultural commodities and associated battles within and around the World Trade Organization (WTO);
2. the effects on world market prices, especially for food, of futures trading in agricultural commodities, that is,

speculation spurred by financial firms (banks, hedge funds, etc.);
3. the removal of subsidies and other forms of support to small farmers in the South as 'austerity' measures required by neoliberalism, together with reduction of government and aid budgets for most farming in the South;
4. the increasing concentration of global corporations in both agricultural input and output industries, marked by mergers and acquisitions and the economic power of fewer corporations commanding larger market shares;
5. new organizational technologies deployed by these corporations along commodity chains from farming thru processing and manufacturing to retail distribution, e.g., the 'supermarket revolution' in the global sourcing of food and market shares of food sales, now extending to some parts of the South;
6. the combination of these organizational technologies with corporate economic power to shape and constrain the 'choices' of farmers and consumers;
7. the push by corporations to patent intellectual property rights in genetic plant material, under the provisions of WTO on Trade-Related Aspects of Intellectual Property Rights, and what its critics term 'biopiracy';
8. the technical frontier of engineering plant and animal genetic material (GMOs or genetically modified organisms) that, together with specialized monoculture, contributes to the loss of biodiversity;
9. the profit frontier of biofuel production, dominated by agribusiness corporations supported by public subsidies in the USA and Europe, and its effects for world grain production for human consumption, as well as for so-called land grabbing in the South by corporations, financial firms, and the sovereign wealth funds of particular countries (in the Gulf, China, and elsewhere), an example of "accumulation by dispossession" (Harvey, 2003) as, in effect a new wave of 'primitive accumulation';
10. the health consequences, including rising levels of toxic chemicals in 'industrially' grown and processed foods, nutritional deficiencies of 'fast food', the growth of obesity and related illness together with continuing hunger and malnutrition in parts of the South;
11. the environmental costs of all the above, including levels of energy use and their carbon emissions, in the continuing 'industrialization' of food farming, processing, and sales; for example, the distances over which food is trucked, shipped, and air-freighted from producer to consumer; and
12. connected issues of the sustainability or otherwise of the current global food system and its continued growth.

How do these topical concerns connect with, or depart from, the concerns of the 'classic' agrarian question (in Kautsky's term, 1988) concerning the origins of capitalism and its subsequent spread, principally in Western and Eastern Europe? While modern agrarian political economy extended the geographical and historical scope of its research, as noted, in investigating agrarian change in the once colonial and now-independent countries of the South it initially followed the model of the 'classics'. This usually implied an 'internalist' focus on the growth (or 'blocking') of agrarian capitalism (Bernstein, 1996) in the countrysides and rural class structures of individual countries: what was happening with agricultural production? Was agrarian capitalism developing? How, and how much? Was agriculture contributing to industrialization or not? These are the kinds of questions that informed Lenin's (1964) study of Russia in the late nineteenth century, and that were transposed, for example, to India (see the Indian 'modes of production' debate of the 1960s and 1970s collected in Patnaik, 1990). Ironically, while colonialism – and the world economy of which it was part – provided an essential international dimension to arguments of the 'development of underdevelopment' in the South, including 'exploitation' of its peasantries, with political independence attention was often much more focused on the social landscapes 'internal' to its rural areas.

A 'world system' approach at least signaled the importance of the international dimension and its effects for farming and farmers in the South (and indeed the North). Its most significant expression is Friedmann's theorization of 'international food regimes' (IFRs) and her analysis of the two principal IFRs to date in the history of modern world capitalism: the first from the 1870s to1914, and the second from the 1940s to 1970s, with debate whether a third IFR has emerged in the context of globalization since the 1970s. Friedmann and McMichael (1989) outlined a global division of labor in agricultural production and trade that they argue was established from the last third of the nineteenth century.

If 'internalist' and 'world system' perspectives ran in parallel for some decades it seems more difficult to keep them separate now with the reshaping of the world agricultural and food economy in the period of globalization, indicated by the themes listed above and the challenges they present to agrarian political economy in the second decade of the twenty-first century.

Corporate Power and Technology

Of the list of 12 themes above, no fewer than seven directly concern corporate agribusiness (the first, and fourth to ninth) and the other themes are often connected by its critics with global corporate power and its technologies and business strategies – material, organizational, and symbolic (e.g., branding of food commodities). The dangers of corporate power are also closely associated with growing awareness of, and concern with, environmental sustainability as well as social justice.

Ecology

Environmental sustainability has become a major concern in recent decades, generating new fields of ecological economics and political ecology. The former is centered on 'the unavoidable clash' between economy, not least the industrialization of farming, and the environment (Martinez-Alier, 2002: ix). This has had a major impact on agrarian political economy, if unevenly so (as in the case of feminist scholarship earlier, noted above). A major landmark in this respect is the remarkable project of Jason W. Moore to construct a materialist theory and history of capitalism as 'world ecology' (e.g., Moore, 2010).

The idea of the industrialization of farming draws attention to the growing energy use of highly modernized agriculture (mechanization and 'chemicalization') and its "accelerating biophysical contradictions" (Weiss, 2010). For Martinez-Alier (2002), as for many others, the solution is to be sought through political ecology: study of the environmentally more friendly, energy 'efficient', practices of small-scale farmers (albeit at much lower levels of labor productivity). The 'environmentalism of the poor' is proposed as the alternative to the destructive technologies and practices of large-scale, highly capitalized agriculture – comprising food (and biofuel) processing and distribution as well as farming – characteristic of North America, much of Western Europe, Australia, and large agricultural exporters in the South like Argentina and Brazil.

In short, in present circumstances of globalization and its discontents, not least the concern with environmental sustainability, the long-standing tension between advocates of large- and small-scale farming ('taking the part of peasants') is as pertinent as ever and as highly charged as in the past. Contributions to this ongoing debate include arguments for taking an 'actor's perspective' to understand and appreciate better the beliefs and practices of small farmers (Long, 2001), and that 'new peasantries' are emerging, in Europe as well as in the South, who can successfully negotiate their integration with markets and choices of technology from a commitment to 'autonomy' (van der Ploeg, 2008).

Fates of the 'Peasant'/Small Farmer (Once More)

All this suggests that for champions of 'new peasantries', small farmers have not been 'eliminated' by global capitalism but can continue to adapt and to thrive, if typically in constrained circumstances, and, as noted, that they provide the key to any prospects of 'agrarian futures' that are sustainable environmentally as well as more socially just. Moreover, these kinds of claims inform the politics of a range of new agrarian social movements that mobilize regionally, nationally, and in several cases transnationally, of which the best-known example is *La Vía Campesina* ('the peasant way'), which originated in Central America (Borras et al., 2008).

Critics suggest that such claims continue to embody a romantic (populist) vision, that (1) their use of a unitary category of 'small farmers'/'peasants' obscures profound class and gender differentiation and inequality in the countryside; (2) many of those described as 'small farmers' in fact gain most of their livelihood from wage work, often as migrants (e.g., 60% plus of rural people in India are unable to reproduce themselves from their own farming); (3) this reinforces the need to examine agrarian change in the South today in terms of key rural–urban linkages, and agricultural–industrial linkages too (as in the North); (4) that small farmers using relatively simple technologies are unable to feed the rest of the world's population, now so much larger than in past eras of 'peasant' societies and now more than 50% urban.

Agreeableness

Renée M Tobin, Illinois State University, Normal, IL, USA
Daniel L Gadke, Mississippi State University, Mississippi State, MS, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Arguably the largest of the dimensions of the five-factor approach to personality, agreeableness is the motive to maintain smooth interpersonal relationships. Longitudinal research suggests stability in agreeableness across the lifespan. It is theorized to have developmental origins in the temperamental process of effortful control and has been linked to positive social behaviors including helping, cooperation, and emotion regulation. It has also been connected inversely to maladaptive social behaviors including aggression, conflict, and prejudice. Application of the Opponent Process Theory is used to explain the relations between agreeableness and social behaviors.

This article focuses on agreeableness as a dimension of personality. In it, we define agreeableness and detail its measurement methods. We also review developmental and theoretical accounts of this individual difference as well as the dimension's relations to adaptive and maladaptive social behaviors. Finally, we provide a theoretical account to aid in understanding the links between agreeableness and diverse social behavior.

Personality is the collection of stable characteristics that constitute an individual. Social scientists, especially psychologists, have long been interested in determining the core individual differences that comprise personality. Although there is some dissent about the structure of personality, the Five-Factor Model of Personality, also known as the Big Five, is widely regarded as the most accurate representation of the dimensions of human personality (McCrae and John, 1991). These five factors include agreeableness (e.g., generous, trustful, giving), extraversion (e.g., active, talkative, gregarious), conscientiousness (e.g., organized, ethical, thorough), neuroticism (e.g., anxious, self-defeating, unstable), and openness to experience (e.g., curious, introspective, intellectual; McCrae and John, 1991).

Based on factor analyses of six major data sets, Digman and Takemoto-Chock (1981) found that "friendly compliance vs. hostile noncompliance" was the first and largest factor of personality to emerge. This factor is labeled agreeableness. Agreeableness is described as the motive to maintain smooth interpersonal relations with others (Graziano and Eisenberg, 1997). "More formally, agreeableness is defined as a superordinate summary term for a set of interrelated dispositions and characteristics, manifested as differences in being likable, pleasant, and harmonious in relations with others" (Graziano and Tobin, 2013: p. 347). Research indicates relative stability in agreeableness, such that individuals who are kind early in development tend to be seen as warm, empathic, and cooperative as adults.

In 1997, Graziano and Eisenberg authored a groundbreaking chapter on agreeableness, linking it to theory and research on altruism, prosocial behavior, and motivation. When the chapter was published, little research had been conducted on this major dimension of personality; however, since its publication, research on agreeableness has increased significantly. A PsycINFO search conducted in October 2013 revealed a total of 459 peer-reviewed papers when agreeableness was entered as the keyword. Of that total, only 11 were published before 1997. These articles about agreeableness range in topic, focus, and method, with the majority reporting correlational outcomes for studies designed to examine something other than this personality dimension. Fortunately, beyond these correlational studies, an empirical literature on agreeableness has also emerged in which scientists have focused explicitly on understanding the processes underlying agreeableness and how this individual difference maps onto overt behavior. The primary goal of this section is to provide readers with a summary of some of the main findings related to individual differences in agreeableness over the last 15 years.

Measuring Agreeableness

Examination of the literature on agreeableness reveals that most studies rely on verbal self-reports of personality. Many different measures of the Big Five are available in many different languages, and these self-reports show remarkable convergence. The most popular commercial product assessing the five-factor approach to personality is the NEO, now on its third edition (Costa and McCrae, 1988). This self-report questionnaire provides five-factor scores with six facets each for individuals between the ages of 12 and 99 years. For agreeableness, the six facets are trust, modesty, compliance, altruism, straightforwardness, and tender-mindedness. Relative to the overall factor of agreeableness, less is known about these smaller facets. In addition to the NEO, a similar measure is available in the public domain through the International Personality Inventory Pool (Goldberg et al., 2006). Other self-report measures with strong psychometric properties are also available to measure the agreeableness dimension (e.g., Big Five Inventory; John and Srivastava, 1999). Beyond self-report, agreeableness (and the other dimensions of the Big Five) has been assessed using ratings from others including spouses (Costa and McCrae, 1988), employment supervisors (Hogan et al., 1996), and teachers/childcare supervisors (e.g., Digman and Takemoto-Chock, 1981; Tobin and Graziano, 2011). It is also possible to measure agreeableness in youth by obtaining

parents' free descriptions of their children (e.g., Kohnstamm et al., 1998) or through parental sorting of statements reflecting the extent to which each describes the child (e.g., Abe, 2005).

Correlations between agreeableness and other dimensions of personality vary by method and measure. Adjective marker methods (e.g., Goldberg, 1992) tend to generate stronger correlations between agreeableness and conscientiousness, whereas questionnaires with sentence formats (e.g., Big Five Inventory; John and Srivastava, 1999) tend to yield stronger correlations between agreeableness and extraversion. Agreeableness is typically inversely related to neuroticism. Studies have been mixed in terms of the relation between agreeableness and gender, with some researches finding no evidence of a relation and others finding higher agreeableness in female participants. Non-American samples and samples of young children tend to yield lower internal consistency scores for agreeableness than do American and European samples (e.g., Soto et al., 2008). Some studies also suggest that less satisfactory internal consistency scores are obtained for agreeableness when abbreviated measures are employed.

Social Desirability Artifact?

One of the most challenging issues facing agreeableness researchers is combating claims that this dimension of personality simply reflects socially desirable responding (SDR). SDR is behaving in a manner that makes the respondent appear more favorable (Graziano and Tobin, 2002). Given that items reflecting higher agreeableness tend be more favorable (e.g., 'has a trusting nature'; 'is kind and considerate of others') than those indicating lower agreeableness (e.g., 'tends to find fault with others'; 'is cool and aloof'), social desirability seems a reasonable concern. Perhaps because of the perception of social evaluation, agreeableness is often mistaken simply for social desirability. As previously discussed, agreeableness is most often measured via self-report measures (e.g., NEO, International Personality Item Pool (IPIP), Big Five Inventory (BF)I, etc.), allowing for SDR to influence self-ratings. To address this concern, Graziano and Tobin (2002) designed three studies.

Graziano and Tobin (2002) empirically investigated the potential link between SDR and agreeableness in a multimethod study. In the first study, the researchers explored the zero-order correlations between agreeableness and three different forms of SDR with a sample of 316 participants: impression management, self-deception, and self-monitoring. They found that agreeableness correlated with SDR, particularly impression management; however, correlations were also found across conscientiousness and neuroticism, suggesting that if there is a problem with agreeableness and SDR, it is one that is shared, perhaps to a greater a degree, with other traits of the Big Five.

In the second study, a round-robin approach was used with 348 research participants. Graziano and Tobin (2002) collected self-reports of agreeableness, extraversion, and SDR. Participants were then randomly assigned to one of three instruction groups: (1) *desirable-to-be-agreeable*, (2) *undesirable-to-be-agreeable*, and (3) a *control* condition. Depending on their group, participants were provided with different instructions about how best to behave. Triads were then formed containing a member of each group. The triads were expected to complete a group decision-making task and then were asked to rate the other members of their group on agreeableness and extraversion. Their results, in short, indicated no evidence of differences in self- or other-ratings across conditions, despite manipulation checks of the instructions. Furthermore, they found no evidence of significant differences across groups based on the three forms of SDR.

In the final study, groups of three research participants were asked to rate the quality of 11 different conflict resolution tactics across a series of vignettes. After practicing with their group on a vignette, groups were randomly assigned to three different social desirability groups: (1) *bad-to-be-agreeable*, (2) *good-to-be-agreeable*, and (3) *control*. The first two groups were given instructions that mapped onto their group placement; the third group was not provided with any instructions. Research participants were also asked to complete measures of agreeableness and SDR. Results were similar to those found in Study 2. That is, there was no evidence that group membership influenced ratings of agreeableness. Taken together, the data across the three studies lend little evidence to suggest that SDR accounts for ratings of agreeableness. Graziano and Tobin (2002) note that agreeableness is not "easily manipulated or distorted by SDR" (p. 696).

Theoretical Accounts of Agreeableness

Conceptually, agreeableness is often defined in terms of social motivation (i.e., the desire to maintain smooth interpersonal relations with others; Graziano and Tobin, 2013). It has also been theorized that agreeableness has developmental roots in the regulatory process of effortful control (Ahadi and Rothbart, 1994). As defined by Ahadi and Rothbart (1994), the temperamental process of effortful control is the ability to suppress a dominant response in favor of a subdominant one. This temperamental process is considered the foundation of regulation within adult personality, particularly individual differences in agreeableness in dealing with persons and conscientiousness in dealing with tasks or objects.

The theoretical foundation of effortful control has been substantiated in the empirical literature from preschool through emerging adulthood. In general, research indicates that effortful control is positively related to agreeableness (Abe, 2005; Cumberland-Li et al., 2004; Jensen-Campbell et al., 2002). Cumberland-Li et al. (2004) found that teacher and parent ratings of effortful control were related to teacher ratings of agreeableness in preschool-aged children. In a longitudinal study, Abe (2005) found that parental Q-sorts (i.e., sorting of descriptive terms into piles that apply more or less to the child) of agreeableness at age 3.5 years was related inversely to displays of negative affect at age 5, and to parent ratings of impulsive-hyperactive and conduct problems in adolescence, suggesting that early ratings of children's motives to maintain positive interpersonal relationships map onto immediate and distal regulation. Tobin and Graziano (2011) found that school-aged children high in agreeableness regulated their negative emotional reactions to disappointment more than their peers did.

Similar relations are found later in development. For example, Tobin et al. (2000) found that college students who were higher in agreeableness experienced stronger negative emotions, but they also made greater efforts to regulate these emotions when presented with emotionally evocative, negatively valenced images. Similiarly, Jensen-Campbell et al. (2002) found that college students who were high in agreeableness performed better than their peers on neurological tests associated with control behavior (e.g., Stroop test and Wisconsin Card Sorting Task), suggesting that effortful control is a common developmental substrate of agreeableness. Haas et al. (2007) examined self-reports of agreeableness as a predictor of right lateral prefrontal cortex activation, the part of the area in the brain thought to control the conscious regulation of negative affect. Using functional magnetic resonance imaging, these researchers found a direct positive relation between agreeableness and the activation of the right lateral prefrontal cortex, suggesting that individuals who are high in agreeableness are wired to regulate emotion more effectively than their peers when presented with certain emotionally evocative stimuli (i.e., fearful faces).

In a longitudinal study, Laursen et al. (2002) examined the relations between agreeableness and regulation-related behaviors. Specifically, they collected teacher and peer reports of aggression, compliance, and self-control beginning at age 8. They found that these same variables distinguished adults as high and low in agreeableness at age 33. Based on profile analysis, these researchers found two behavioral types in childhood and two personality types in adulthood, with considerable continuity in the composition of these groups over time. Fewer disobedience and concentration problems were present in high-agreeable childhood types than low-agreeable childhood types. Among boys, better school grades and fewer behavior problems were present in high-agreeable childhood types than their low-agreeable counterparts. Less alcoholism and depression, fewer arrests, and more career stability characterized the high-agreeable adulthood types relative to the low-agreeable adulthood types. From these patterns, Laursen et al. concluded that these differences in agreeableness are stable from childhood to adulthood, and are linked to important regulatory processes that lead to advantages to those children, relative to their peers, over time.

Linking Agreeableness to Social Behaviors

The literature is rich with examples of the predictive utility of agreeableness. As mentioned previously, it is arguably the largest of the five factors (i.e., Digman and Takemoto-Chock, 1981), and it is directly related to an individual's ability to control his or her emotions and related behaviors across development (e.g., Cumberland-Li et al., 2004; Tobin and Graziano, 2011; Tobin et al., 2000). Additionally, the empirical support for agreeableness as a predictor variable for overt behavior extends to include, but is not limited to, behaviors such as cooperation, helping, and conflict resolution. This section is not intended to be an exhaustive review of the literature linking agreeableness to overt behavior; rather, it provides a survey of selected behaviors with considerable research support.

Friendship

Not surprisingly, agreeableness has been directly linked to peer acceptance and friendship. In a multicomponent study, Jensen-Campbell et al. (2002) investigated agreeableness as a predictor of initiating and maintaining friendships in groups of fifth and sixth grade participants. In their initial study, participants were asked to complete measures of personality and self-esteem. Additionally, the researchers used peer nominations, asking the participants to list their five best same-sex friends in their grade and school. These reports were used to generate composite peer acceptance and friendship scores. As expected, agreeableness was directly related to higher composite scores for both peer acceptance and friendship such that participants high in agreeableness had higher composite scores of both.

The second study built on the first using a modified version of the peer nomination form. On the new peer assessment form, participants rated their classmates across several questions that mapped on to the superordinate domains of victimization, physical strength, externalizing behaviors, internalizing behaviors, and prosocial skills. Participants completed this measure in both the fall and spring to allow for the calculation of change in ratings over time as they related to personality. The results revealed that participants rated as high in agreeableness were initially given lower ratings of victimization. This remained true when reevaluated in the spring. Additionally, high agreeableness scores were associated with lower behavioral risk factors over the course of the year (e.g., weakness, internalizing behaviors). Taken together, these studies suggest that high-agreeable students are more likely to be identified as friends (i.e., higher friendship ratings), be less victimized, and overall have less behavioral risk factors as identified by their peers. This comes as no surprise given Graziano and Eisenberg's (1997) hypothesis that agreeableness evolved out of a need for groups to get along and survive together.

Cooperation and Competition

Agreeableness has been linked to differential responding to cooperative and competitive tasks. In a multicomponent study, Graziano et al. (1997) explored the relations among agreeableness, competitiveness, and behavior during games with different goal structures. In the initial study examining expectations, Graziano and his colleagues found that individuals high in agreeableness anticipated problems associated with goal-oriented competitive situations relative to their peers. In a follow-up study, the researchers placed participants in same-sex triads to examine their behavioral responses to a tower-building task. The triads were comprised either two individuals rated as high in agreeableness and one individual rated low in agreeableness, or of two individuals low in agreeableness and one individual high in agreeableness (i.e., A+A+A− or A−A−A+). The triads completed 12 trials of a tower-building task as a group and behavior was examined at the individual and group level. Triads were randomly assigned to complete the task in either a promotive or contrient goal structure condition. In the promotive condition, participants equally benefited from the triad's collective performance. In

contrast, triads in the contrient condition competed with one another, with only one member of the triad receiving a reward for each trial. At the study's conclusion, each member was asked to evaluate him- or herself and the other group members. Results of the second study indicated that individuals low in agreeableness display more competitive behaviors than individuals high in agreeableness. Further, the researchers found that competitiveness acts a mediator between agreeableness and group cooperation, such that low-agreeable individuals do not view themselves as interdependent with the group and are more competitive in response to goal structures relative to high-agreeable individuals. Additionally, overall results of Graziano et al.'s (1997) studies suggest that agreeableness is related to individual differences in competitive group behavior.

Building on this work, Tobin et al. (2002) conducted a similar study with school-aged children and found consistent results. Using a within-subjects design, Tobin and colleagues found individuals high in agreeableness foster cooperation among the group even in competitive situations. They also found greater cooperation in groups as group-level agreeableness increased. In a web-based study of adults, Hilbig et al. (2013) also found that agreeableness was related to non-retaliatory cooperation. Taken together, these studies provide evidence of the connection between agreeableness and cooperative behaviors across age groups.

Helping

Agreeableness has been linked to prosocial behaviors such as helping and empathy. Across a series of four studies, Graziano et al. (2007a) explored the links between prosocial motives, helping, empathy, and personality. In the first study, participants provide ratings of their likelihood of helping in two situations: everyday helping (i.e., being late for work to help a person whose car had broken down on the side of the road) and extraordinary helping (i.e., entering a burning house to save an individual trapped inside), depending on whether the person in need of help was a sibling, friend, or a stranger. Results indicated that individuals high in agreeableness are generally more likely to help others than their peers are. When relationships are taken into consideration, individuals high in agreeableness are more likely to help a friend or a sibling than their peers are in everyday helping situations. In extraordinary helping situations (i.e., entering a burning building), high-agreeable individuals were more likely to help a stranger than their low-agreeable peers, but there was no difference between the two groups regarding their likelihood in saving a friend or a sibling. Thus, in everyday situations high-agreeable individuals may be more likely to help people they know, but in extreme circumstances, high-agreeable individuals are also more likely to potentially risk their life to save a complete stranger.

In the second study, participants listened to a radio broadcast featuring a female college student who had recently lost her parents and was struggling to take care of her younger siblings. Prior to listening to the broadcast, participants were randomly assigned to adapt one of two listening perspectives, empathetic (i.e., focusing on the emotional aspects of the broadcast) or technical (i.e., focusing on the production aspects of the broadcast) perspective. Participants were also randomly assigned to an in-group versus out-group condition: the student attended the same university or a different university as the participant. Following the broadcast, researchers informed the participants that the broadcast would not be shared with the public and then provided an opportunity to help the student. Results indicated that participants high in agreeableness were more likely to help the girl when she was part of the out-group (i.e., attended a different university) than were low-agreeable peers; however, there was evidence of a difference in willingness to help when the girl was part of the in-group. Additionally, individuals high in agreeableness in the technical perspective condition were more likely to provide help to the girl than individuals low in agreeableness in that condition. Finally, consistent with other studies, participants high in agreeableness were more likely to rate the student as similar to themselves than their peers were. Together, these results suggest that high-agreeable individuals may be likely to help members of different groups than their own, express empathy and helping, and are more likely to take a similar perspective and identify individuals in need than low-agreeable individuals are.

Graziano et al.'s (2007b) third study used an identical paradigm to that of Study 2, with the addition of an emotional reaction questionnaire. The questionnaire asked participants to rate their own emotions, empathic concern, and personal distress after hearing the broadcast, but prior to knowing they would be able to offer help. Results indicated that the effects of agreeableness were only noteworthy on willingness to help for those who expressed empathic concern, but this difference was only detected in the technical perspective condition.

In a fourth and final study, Graziano et al. (2007b) used this paradigm again, with the addition of a cost-of-helping variable. Participants were randomly assigned to a high cost of helping or a low cost of helping condition. In the high cost of helping, participants were told that if they volunteered it had to be for a minimum of 5 h and they could only increase their amount of time in 5-h increments. In the low cost of helping condition, individuals were able to choose to volunteer anywhere between 1 and 20 h. Results indicated that individuals high in agreeableness did not differ in their willingness to help regardless of the cost to their time. There was, in contrast, a notable difference in the helping behavior for individuals low in agreeableness. In the empathy-focused condition, when the cost of helping was low, low-agreeable individuals helped more than when the cost was high. Furthermore, low-agreeable individuals helped less in the empathy perspective condition in comparison to those in the technical perspective condition when costs were high. Finally, in the technical perspective condition only, individuals low in agreeableness helped more when the cost was high than when the cost was low. Although the results may be surprising, they suggest that individuals low in agreeableness are willing to help less when cued to empathetic concerns or markers, particularly if the cost is high. Graziano and colleagues (Graziano and Habashi, 2010; Graziano and Tobin, 2009, 2013) explain this pattern of findings by connecting it to the Opponent Process Theory detailed later in this article. Overall, this collection of studies suggested that the foundation of prosocial motivation underlying agreeableness is related to the experience of empathy, and in turn, to the expression of helping behaviors.

Conflict resolution

Agreeableness has also been linked to conflict resolution. In a multimethod study, Graziano et al. (1996) evaluated the use of 11 different conflict resolution tactics across five different types of relationships (i.e., parents, siblings, roommates, significant others, and friends) using college-aged research participants. The 11 different tactics mapped on 3 primary categories: power assertion, negotiation, and disengagement. Results from the initial study indicated that regardless of a participant's level of agreeableness (i.e., high vs low), the use of negotiation tactics was rated as the most effective means of resolving conflict. Additionally, individuals low in agreeableness endorsed power assertion tactics as more effective at resolving conflict than did their high-agreeable peers. Finally, individuals low in agreeableness were more likely to respond differentially about the appropriateness of specific conflict resolution tactics based on the relationship (e.g., parents, siblings) than were individuals high in agreeableness. For example, individuals low in agreeableness endorsed power assertion tactics when dealing with siblings and friends, but endorsed negotiation for parents and significant others. In contrast, individuals high in agreeableness endorsed negotiation as best across all relationship types.

In the second Graziano et al.'s (1996) study, participants were placed in dyads to resolve social conflicts. Findings suggest that individuals high in agreeableness perceived less conflict, liked others more, and were more likely to give their partners positive ratings following the interaction. In contrast, individuals low in agreeableness actually elicited more conflict from partners than their peers did. This finding was particularly strong for male participants who were low in agreeableness, as they were more likely to perceive, engage in, and elicit conflict from their partners than were males who were high in agreeableness.

These relations are also found earlier in development. Building on their previous work, Jensen-Campbell and Graziano (2001) used a similar paradigm with children in middle school. Importantly, they also examined these relations using a diary methodology that allowed for a more complete understanding of these processes in daily life. In this study, school-aged participants were trained to record their interactions throughout the day using a standardized recording instrument. Participants rated every interaction that lasted more than 10 min and every conflict, regardless of length, on a specified day. Conflicts included everything from a simple disagreement to physical altercations. These interactions were rated by the participants on a scale of 1 ('not angry at all') to 7 ('very angry'). Their responses were categorized by researchers as constructive tactics, destructive tactics, negative affect, and outcomes (i.e., problem solved and continue to interact with conflict partner). Overall, children rated as higher in agreeableness on self and teacher reports were more likely to endorse the use of negotiation than their peers low in agreeableness, who were more likely to endorse power assertion tactics. Specific outcomes from the diary collection indicated an inverse relation between agreeableness and anger and hurt feelings. Agreeableness was also positively related to interpersonal adjustment, as measured by the diary data.

Finally, Jensen-Campbell et al. (2003) examined the relation between agreeableness and conflict in a multimethod study. The first study involved the use of questionnaires, including one on which participants rated the appropriateness of similar conflictresolution tactics. Consistent with earlier findings, agreeableness was positively related to the use of constructive tactics and inversely related to destructive tactics. In the second study, Jensen-Campbell and her colleagues placed children in dyads to play a board game together. In these dyads, each member was supplied with a conflicting set of rules to promote a conflict interaction between the two. After the game, participants rated their perception of the game and their partner in efforts to measure their perception of conflict. Consistent with previous studies, children high in agreeableness, regardless of the rules they were given or with whom they were partnered, were less likely to perceive conflict and endorse destructive tactics than their low-agreeable peers.

Aggression

The link between agreeableness and aggression has also been explored in recent years. Gleason et al. (2004) investigated agreeableness as a predictor of aggression in middle school children using a multimethod study. In their first study, the researchers measured self-reported direct and indirect aggression. In the second study, they examined the relation between social cognitions associated with aggression and peer reports of direct aggression. Results from the first study revealed an inverse relation between agreeableness and aggression. Specifically, adolescents rated as high in agreeableness reported lower rates of both direct and indirect aggression. They found the strongest relation between agreeableness and direct aggression, suggesting that individuals high in agreeableness try to avoid acts of direct aggression. The second study substantiated these findings further, replicating that agreeableness was indirectly related to direct aggression as reported by peers. Finally, the second study also found that agreeableness was indirectly related to aggressive social cognitions. That is, participants rated as high in agreeableness were more concerned about the use of aggressive tactics than were their peers low in agreeableness.

Consistent with these findings, Tremblay and Ewart (2004) found a significant inverse relation between agreeableness and both physical and verbal aggression in a correlational study of 246 undergraduate students. Using a different approach, Ode et al. (2008) conducted three studies to systematically examine agreeableness as a moderator of the relation between neuroticism and aggression. Across these three experimental studies, these researchers found that the neuroticism-aggression link was reduced at higher levels of agreeableness. Overall, research indicates that agreeableness is inversely related to aggressive thoughts and behaviors.

Prejudice

Agreeableness is also related to differential reactions to others. In a multistudy article, Graziano et al. (2007a) investigated the relation between agreeableness and prejudice toward a female who is overweight. First, these researchers examined agreeableness as a predictor of reactions toward over 100 potential targets of prejudice, finding that agreeableness was related

inversely to personal endorsements of prejudice. Importantly, they found no evidence that agreeableness was related to perceived social norms. That is, individuals high in agreeableness did not differ from their peers in terms of understanding the social norms about the acceptability of holding prejudiced feelings toward these groups, but they did differ in their personal endorsement of such prejudice. Specifically, individuals high in agreeableness reported less negative reactions to most groups, including traditional targets of prejudice (e.g., homosexuals, Jews, Hispanics) relative to their peers.

In subsequent studies, these researchers examined potentially prejudicial reactions to specific interaction partners. In the second study, participants were randomly assigned to view the photograph of either a typical or overweight female partner with whom they were scheduled to interact over the telephone. Following conversations, participants completed a social distance measure about their partners. Results indicated that male participants low in agreeableness responded with the most prejudicial reactions, but only when partnered with an overweight woman. In the third study, the researchers replicated and extended these findings by showing that these prejudicial reactions also led to discriminatory behaviors. That is, when given an opportunity to change interaction partners, only men low in agreeableness wanted to switch partners, and they only did so when paired with an overweight female partner.

Graziano et al. (2007a) then examined whether situational differences would influence the prejudicial behavior of individuals high in agreeableness. They found that overall individuals low in agreeableness expressed more prejudice than those high in agreeableness, but that some conditions seemed to elicit these types of reactions from individuals high in agreeableness as well. Specifically, they found that individuals high in agreeableness would express prejudice toward a woman who is overweight when she is thought to have engaged in counter-normative behavior (e.g., expressing negative views of the university) or she creates more work for the participant. In contrast, individuals low in agreeableness expressed more negative reactions to their partners regardless of her expressed beliefs or the cause of additional work. Taken together, these findings suggest that agreeableness is linked to more positive reactions to others, including those who are considered targets of prejudice.

Opponent Process Theory

Graziano and colleagues (Graziano and Habashi, 2010; Graziano and Tobin, 2009, 2013) have used the Opponent Process Theory (Solomon, 1980) to help explain the processes underlying agreeableness. This model, shown in **Figure 1**,

Figure 1 Opponent process model of motivation. Adapted from Solomon, R.L., Corbit, J.D., 1974. An Opponent-Process Theory of motivation: I. Temporal dynamics of affect. Psychological Review 57, 119–145.

specifically describes how two processes are activated and unfold over time. In this model, Process A is considered dominant and is characterized by almost automatic responding. Process B, although less dominant than the automatic Process A, activates shortly after and persists beyond Process A. The persistence of process B beyond A leads to the behavioral manifestation of Process B. Although Solomon (1980) used this model to describe cycles of addictive behavior, it also works well in explaining the behavioral manifestations of agreeableness, such as helping and prejudicial behaviors (Graziano and Habashi, 2010; Graziano and Tobin, 2009, 2013). For example, in the case of helping behavior, Process A is distress or self-focused negative affect and Process B is empathy. When confronted with a person in need of help, Process A (self-focused negative affect) is immediately activated, leading to the desire to escape (identified by Dijker and Koomen, 2007, and others, as the *flight-fight system*). If the individual does not escape the situation, Process B (empathy) will be activated (mapping onto the *care system*; Dijker and Koomen, 2007). Graziano and colleagues hypothesize that for individuals high in agreeableness, the onset of Process B is faster than it is for those low in agreeableness; thus, they more readily engage in empathic concern, and helping behavior follows. It appears that Process B is slower to initiate in individuals low in agreeableness relative to those high in agreeableness, leading to less helping behavior.

As mentioned earlier, these authors have also applied this model to prejudicial behavior, suggesting its usefulness in explaining a range of behaviors. Given the nature of agreeableness, it is not surprising that the motive of social accommodation would take on many forms. Metaphorically, rather than a single switchblade, agreeableness is more like a Swiss Army knife with multiple components available to handle any social situation as needed to maintain good relations. Future research on agreeableness would benefit from explorations of these relations in controlled studies that manipulate (or at least measure) aspects of these processes in fine-grained detail over time.

Agricultural Sciences and Technology

Abstract

The agricultural sciences include the plant, animal, and food sciences; soil science; agricultural engineering and entomology; as well as related fields such as agricultural economics, rural sociology, nutrition, forestry, fisheries, and home economics. Historians, economists, sociologists, and philosophers have all studied agricultural sciences and technology, although there are few links among these four approaches. Current studies include those of biotechnologies, nanotechnologies, relations between science and colonialism, returns to agricultural research, and the relations between public and private research in agriculture.

Introduction

The agricultural sciences and technology are usually seen to encompass the plant, animal, and food sciences; soil science; agricultural engineering; and entomology. In addition, in many research institutions related fields such as agricultural economics, rural sociology, human nutrition, forestry, fisheries, and home economics are included. The agricultural sciences have been studied by historians, economists, sociologists, and philosophers.

Most of the early work in Science and Technology Studies (STS) focused on physics, said to be the model for the sciences. Unlike the agricultural sciences, theoretical physics appeared disconnected from any clear social or economic interests. Indeed, one early study of the agricultural sciences described them as deviant in that they did not follow the norms found in physics (Storer, 1980[1961]). (Much later, further studies in STS revealed that even physics did not follow the norms claimed for it and was strongly influenced by military and industrial needs.)

Prior to the 1970s, studies of the agricultural sciences tended to be apologetic and uncritical. Then, critical historical, economic, sociological, and philosophical studies of the agricultural sciences began to emerge. These studies built on earlier work that was not within the purview of what usually is called STS. Moreover, despite attempts to incorporate perspectives from this field, it would be an exaggeration to say that studies of the agricultural sciences form an integrated body of knowledge. Indeed, fragmentation has been and remains the rule with respect to theoretical frameworks, research questions, and methods employed.

History

Recent historical studies have challenged the hagiographical approach of official histories, demonstrating how the organizational structure of agricultural science encouraged particular research strategies and products. Of particular import were studies of the role of the state-sponsored botanical and zoological gardens, and later the agricultural experiment stations, in the colonial project as well as within Europe and North America. In particular, historians began to document the close relations between the rise of economic botany as a discipline and the creation of botanical gardens in the various European colonies in the seventeenth century (Drayton, 2000). Such gardens served simultaneously to further the classification of botanical species and the colonial project by identifying plants of economic value that might serve to valorize the new colonies. Coffee, tea, cocoa, rubber, sugar, and other crops were developed as plantation crops and soon thrived in regions far from their locations of origin. In so doing, they provided revenue for colonial governments and profits for the emerging large colonial trading companies.

In the late nineteenth century, botanical gardens were superseded by agricultural experiment stations in most industrialized nations and their colonies. Until the World War II, the agricultural experiment stations were *the* model and often the sole recipient of government support for nonmilitary scientific research. The experiment stations focused on increasing yields of food crops in Europe and North America, thereby keeping industrial wages down through cheap food and avoiding feared Malthusian calamities. At the same time, the experiment stations in the colonies focused their efforts on increasing yields of exports so as to provide a steady supply of raw materials to European industries. For example, the Gezira scheme in the Sudan combined science, commerce, and irrigation so as to provide long staple cotton for the Lancashire mills (Barnett, 1977).

In contrast to most plant and animal research, mechanical and chemical technologies (e.g., farm equipment, fertilizers, pesticides) in agriculture were developed by private companies. Of particular note is that World War I and especially World War II resulted in technical innovations that made cheap nitrogen fertilizer available in much of the industrial world. This was the case because after the war demand for ammonium nitrate for bombs declined; with relatively small investment, the same facilities could be used to produce fertilizer. As a result, over the past century, the agricultural sciences and technologies played an important role in increasing agricultural productivity per hectare and per hour of labor. However, some argue that this was only accomplished by displacing vast agrarian populations and increasing environmental degradation.

In contrast, recent work suggests that European nations were successful in developing technologies that improved the lives and yields of small farmers in the early twentieth century (Harwood, 2012). Apparently, considerable successes were achieved in Germany and Austria among other places by directly involving farmers in plant breeding and making traits desired by farmers central to plant breeding. However, these successes were gradually supplanted by more 'scientific' approaches to breeding, separating users from scientists institutionally and distinguishing scientific from farmer knowledge and practices. As a result, when Green Revolution technologies were introduced in the developing world in the 1960s and the 1970s, a more top-down approach was taken. Only in the mid-1970s did serious criticism of the Green Revolution become institutionalized in the form of participatory plant breeding (e.g., Trouchea et al., 2012), farming systems research (e.g., Darnhofer et al., 2012), and agroecology (e.g., Gliessman, 2013), although those involved in these developments were rarely aware that many of the same approaches had been used nearly a century earlier. Importantly, each of these changes was led by social scientists, often leading to internal disputes within agricultural research organizations, and most certainly challenging the dominance of biological scientists (especially plant breeders) in the agricultural research hierarchy. However, by the late twentieth century, such approaches had once again been relegated to the sidelines, as the new biotechnologies took center stage.

Economics

While economic studies as early as the 1930s celebrated the products of agricultural research and emphasized 'adjustment' to the new technologies by farmers, the newer literature has focused primarily on the social rates of return to agricultural research. Many such studies have been used to lobby for additional public support for research. Recent work suggests that rates of return may have been overestimated, due to misspecifications and lag times between research and development. That said, returns are still estimated to be as much as 10% per annum (Alston et al., 2011). In contrast, critics of this approach have argued that only the benefits are estimated, while many of the costs are excluded as they are difficult to measure (e.g., acute pesticide poisoning, environmental damage, and research programs yielding few or no results).

Another strand of research in economics is based on the 'technology treadmill' theory, developed initially by Willard Cochrane (1993). Proponents of the theory argue that the market structure for undifferentiated agricultural commodities (e.g., wheat, maize) is such that farmers are always price takers. In practice, this means that they cannot raise prices beyond the market price that is set by demand from a few large buyers (a monopsony). Accordingly, the only way to increase one's income is to adopt new technologies that increase yields without raising production costs. Early adopters are often able to benefit from the use of such technologies in terms of higher returns on their investment. Moreover, they can use those returns either to expand their farms (thereby reducing the number of farms and farmers) or to invest in further cost-reducing innovations. However, as most farmers adopt the new technologies, prices decline accordingly. Hence, farmers find themselves on a technology treadmill. Adopting each technical advance allows them to produce more, but as the majority of farmers adopt the new technologies, the prices they receive decline once again. This, in turn, forces them to find yet newer technologies that will allow them to maintain their rate of profits. Those who cannot manage to keep up on the treadmill are forced out of the market, resulting in consolidation and fewer agricultural producers.

More recently, the theory of 'induced innovation' has been developed as an explanation for the directions taken in agricultural research (Hayami and Ruttan, 1985). Proponents of this framework argue that innovations are induced by the relative scarcity of land, labor, and capital. Thus, in Japan, where land is scarce, research has focused on increasing yields per unit of land. In contrast, in the United States, where labor is scarce, research has focused on increasing yields per unit of labor. The theory further asserts that agricultural research is responsive to demands of farmers as voiced in the political sphere, since much agricultural research is publicly funded. However, critics have argued that this is only likely to be true in democratic regimes (Burmeister, 1988; Plucknett et al., 1990).

Others have examined the allocation of research support across commodities, directing particular concern to what has come to be known as the problem of spillover. Since much public agricultural research has focused on the creation of products and practices that are not protectable by patents or copyrights, research completed in one nation or region can often be used with only minor adaptation in other locales. Economists have concluded that developing nations should not engage in research on commodities with high spillover, such as wheat, but should instead rely on other nations and international agricultural research centers for such materials. They argue that such nations would be served better by investing in research on commodities not grown elsewhere.

Others have argued successfully for the formation of international networks for research on particular commodities so as to spread the costs of research over several nations with similar agroecological conditions (Plucknett et al., 1990). Such networks have been effectively used to exchange information and materials as well as to foster collaboration. However, with the rise of stronger intellectual property rights in agriculture over the past several decades (including plant variety protection as well as utility patents for life forms), there is some evidence that spillovers may be on the decline. In addition, materials transfer agreements are now required to engage in certain kinds of research; often these agreements limit who can use the materials and for what purposes. Indeed, bringing many products of biological agricultural research to market now often requires the permission of numerous patent holders, thereby increasing both time and costs involved.

Another area of interest to economists has been the division of labor between public and private financing of agricultural research. While some economists have argued that biological (as contrasted with chemical and mechanical) agricultural research is by definition a public good, others argue that recently enacted stronger intellectual property rights make it possible for the private sector to shoulder most of the burden for such research. They have attempted to build the case that stronger intellectual property rights create incentives for private

firms to invest in biological research (e.g., plant and animal biotechnologies, seed production), leaving only research in the social sciences and natural resource management to the public sector. Indeed, some nations (e.g., the United Kingdom) have privatized part or all of their agricultural research with varying degrees of success. However, recent evidence from the United States, where the private sector now outspends the public sector, suggests that private sector research tends to focus on commodities and technologies with the highest expected private returns (e.g., maize, soybeans, cotton), leading to investment in a smaller range of research topics and greater emphasis on short-term gain (King et al., 2012). The growth in public–private partnerships tends to exacerbate this trend, as these partnerships tend to emphasize commodities of interest to the private sector. In consequence, declining public funding means that many critical research issues now go unaddressed.

Finally, related to the division of labor is the issue of alternative public funding mechanisms. Traditionally, agricultural research has been funded institutionally, based on annual lump-sum, formula-based appropriations. However, in recent years, there has been a shift toward more project-based grant programs in which scientists compete to receive grants. Proponents of competitive grants argue that this approach ensures that the best research is conducted by the most competent scientists. In contrast, proponents of institutional funding argue that agriculture is fundamentally place based, necessitating that investigations be distributed across differing ecological zones. They also note that competitive grants tend to be funded over just a few years, while much agricultural research requires a decade or more to complete and that the competition process itself is costly, especially when success rates are low. Furthermore, when competitive and formula funding are compared with respect to their impact on agricultural productivity, formula funds appear to have a much greater impact (Huffman and Evenson, 2006).

Sociology

In sociology, adoption–diffusion theory was the dominant approach through the 1960s (Rogers, 1995). Diffusion theorists accepted the products of agricultural research as wholly desirable. Hence, their work focused almost exclusively on the fate of innovations designed for farm use. They employed a communications model adopted from engineering in which messages were seen to be transmitted from the sender to the receiver, later adding the engineering term 'feedback' to describe receivers' responses to the messages sent to them. They argued that adoption could be best understood as based on the social psychological characteristics of adopters and non-adopters. Early adopters were found to be more cosmopolitan, better educated, less risk averse, and more willing to invest in new technologies than late adopters, pejoratively labeled 'laggards'. This perspective fit well with the commitments of agricultural scientists to transforming agriculture, making it more efficient and more modern. However, it ignored the characteristics of the innovations. Often they were large, costly, and required considerable skill to operate and maintain. Not surprisingly, those who rejected the innovations lacked the capital and education to use them effectively.

Later studies challenged the diffusion theorists. First, critics of the Green Revolution asked questions about the appropriateness of the research undertaken (Perkins, 1997). They noted that, although inexpensive in themselves, Green Revolution varieties were often parts of packages of innovations that required considerable capital investment well beyond the means of the average farmer. While acknowledging that yields increased, they documented the considerable rural upheaval created by the Green Revolution: growing farm size, displacement of both small farmers and landless laborers to the urban slums, declining status of women, declining water tables due to increased irrigation, impaired air quality, and contamination of ground water from agricultural chemicals.

Others asked how agricultural scientists chose their research problems (Busch and Lacy, 1983). They noted that science and commerce were necessarily intimately intertwined in agriculture, in the choice of research problems, in the institutional relations between the public and private sectors, and in the value commitments of scientists (often from farm backgrounds) and wealthier farmers (who often have a disproportionate influence on research directions). They challenged the engineering model of communication, seeking to substitute for it one drawn from the hermeneutic–dialectic tradition. Drawing on philosophers such as Jürgen Habermas and Hans-Georg Gadamer, they asserted that communications between scientists and the users of the products of agricultural research had to be able to debate fundamental assumptions about what constitutes a desirable future for agriculture as well as specific technical details.

Sociologists have also studied agricultural commodity chains, i.e., the entire spectrum of activities from the production of seed through to final consumption (Friedland et al., 1978). Such studies have examined the complex interaction between scientists and engineers involved in the design of new seeds and equipment and various constituent groups. Unlike the diffusion and induced innovation theorists, proponents of this approach have engaged in detailed empirical analyses of new technologies, challenging the assumptions of the designers. For example, both the tomato harvester and the hard tomato needed to withstand mechanical harvesting were built on the initiative of scientists and engineers in the public sector rather than to meet any need articulated by growers. Together, these technologies transformed tomato production in many parts of the world by reducing the number of growers and farm workers while increasing farm size. Given the limited employment opportunities of those displaced, critics question whether this was an appropriate investment of public funds.

In recent years, sociologists have devoted considerable attention to the new agricultural biotechnologies (e.g., gene transfer, plant tissue culture), especially those involving transformations of plants. It is argued that these new technologies have begun to transform the creation of new plant varieties by (1) reducing the time necessary for breeding; (2) reducing the space necessary, from large fields to small laboratories, to test for the incorporation of new traits; and (3) making it possible in principle to incorporate any gene into any organism. However, analysts note that the vast sums of private capital invested in this sector stem as much from changes in intellectual property rights as from any advantages claimed for the new technologies. In particular, they point to the advent of plant

variety protection (a form of intellectual property right), the extension of utility patents to include plants, and the imposition of Western notions of intellectual property on much of the rest of the world.

Before these institutional changes, most plant breeding was done by the public sector. Private breeding was not profitable, as seeds are both means of production and reproduction. Thus, farmers could save seed from the harvest to use the following year or even to sell to neighbors. Put differently, each farmer was potentially in competition with the seed companies (Kloppenburg, 1988). In contrast, once the new intellectual property regimes began to be implemented, it became possible to prohibit the planting of purchased seed developed using the new biotechnologies. Suddenly, the once barely profitable seed industry became a potential source of profits. Agrochemical companies rapidly purchased all the seed companies capable of engaging in research in hopes of cashing in on the new opportunities. The result has been a shift of plant breeding research for major crops to the private sector and strong prohibitions on replanting saved seed. One unforeseen consequence of this shift is the decline in the number of persons receiving education in plant breeding, as the public sector trains nearly all such persons. As a result, seed companies are having some difficulty in staffing their operations.

Another emerging area of interest is the development and use of nanotechnologies in agriculture and food (David and Thompson, 2008). Nanotechnologies take advantage of the novel physical and chemical properties of compounds displayed at the nanolevel. Potential uses here include the use of nanosensors to monitor plant and animal health as well as to promote greater food safety, the nanoencapsulation of certain compounds so as to change or enhance the flavor of foods, nanofilters to remove harmful compounds from water and other liquids, and various forms of packaging that employ nanofilms.

However, at the same time, there is considerable scientific debate over the effects of airborne nanoparticles on human health. Moreover, the unexpected consumer resistance found with respect to food and agricultural biotechnologies has made private actors wary of nanotechnologies. As a consequence, they have simultaneously begun research on their use, bringing some technologies to market, even as they have tended to label these new processes and products in ways that obscure their nanolevel properties. Hence, some observers have argued that the private sector is setting itself up for a repeat of the problems with biotechnologies.

Another line of work has examined particular agricultural scientific practices and institutions. These include precision agriculture methods, which apply new technologies and tools to reduce inputs, costs, and the environmental impacts of agriculture. For example, precision tools can be used to increase input efficiency and thereby reduce fertilizer, pesticide, and water application. Limited adoption has been blamed on the lack of exposure and information; however, the high costs of new tools such as sensors, modified farm equipment, and computers has also been shown to hinder application (Napier et al., 2000).

Sociologists and others are also beginning to examine the rapidly developing application of robotic technology that has started to reshape agricultural production systems. For example, Automatic Milking Systems (AMSs) were introduced in 1992 and have been adopted throughout Western Europe, Canada, and the United States. Milking robots have reshaped relationships between humans, dairy cows, and technology – reducing the need for human labor, allowing cows to determine when they will be milked, and providing a wealth of new data collected and analyzed by sensors and computers. While AMS continue to be adopted by dairy producers, engineers are also working to develop other uses for robots in agriculture such as 'robotic farmhands' that can test soil and water conditions and apply pesticides and fertilizers as needed. Sociologists continue to examine how new innovations in agriculture, such as AMS, change the relationships between humans, technology, and the other biotic organisms (e.g., livestock, crops, bacteria) in production systems.

Some research has also been done on the role of extension services in using technoscience to resolve problems faced by farmers, usually in ways that require little change from the status quo. Hence, extension agents are generally able to grapple better with underproduction than with overproduction. The former requires new, more productive material technologies that have social technologies concealed in them, while the latter usually requires new overtly social technologies – something that extension agents generally try to avoid. Hence, extension agents tend to promote new technologies in part by presenting them as solutions to problems faced by farmers who they see as their primary clientele. In contrast, technologies that might aid farm workers or consumers generally receive less attention. As a result, extension services have played a part in the gradual reduction of the farm population to less than 2% of the total in the United States, even as they have enhanced productivity largely along industrial and commodity lines.

A final area of growing interest to sociologists (and also to economists and philosophers) is the rapid growth of standards, certifications, and accreditations of food and agricultural products and processes. These standards are usually promulgated and enforced by private companies, industry organizations, or private voluntary associations as means of promoting their respective objectives; as such they are alternatives to or supplements for governmental regulations. Often, these standards and certifications are designed to measure technoscientific properties of products and processes (e.g., food safety, Hazard Analysis and Critical Control Points) or use science-based measures to certify that products meet certain standards (e.g., Brix levels in grapes, acceptable colors in fruits and vegetables). Among the many studies in this emerging area are those concerned with (1) particular standards-setting bodies, such as the Codex Alimentarius (Lee, 2009); (2) the consequences of particular standards and/or certifications (Daviron and Ponte, 2005); and (3) the implications of the shift from public to private modes of governance in the agrifood sector (Kimura, 2013).

Philosophy

In recent years, applied ethicists have begun to take an interest in the agricultural sciences, asking a variety of ethical questions about the nature of the research enterprise, its relation to larger

environmental issues such as the conservation of biological diversity, and the distribution of the products generated by the agricultural sciences. Some have asked whether it is even possible to engage in applied science without considering the ethical issues raised by the research agenda. Two interdisciplinary professional societies emerged out of that interest: The Agriculture, Food and Human Values Society and the European Society for Agricultural and Food Ethics. Each now regularly publishes a journal that addresses these issues.

In a major contribution to the field, Thompson asserts that agriculture is dominated by what he calls the 'productionist ethic', the belief that production is the sole metric for ethically evaluating agriculture (Thompson, 1995). From this perspective, derived from the philosophical work of John Locke, land not in cultivation is wasted. Agricultural scientists, themselves often from farm backgrounds, have posited this as self-evident. This was combined with a positivist belief in the value-free status of science and a naive utilitarianism that assumes that all new technologies adopted by farmers are ethically acceptable. From this vantage point, all distributive issues are to be resolved by making the pie bigger. Similarly, environmental problems are defined as arising from inadequate technologies. In contrast, Thompson proposes an ethic of sustainability in which agricultural production is embedded in environmental ethics. He links this to Aldo Leopold's land ethic, which stresses that our notion of community needs to be expanded so as to include the land, place, and other living inhabitants. That said, he notes that the quest for sustainable systems will be filled with both ironies and tragedies (Thompson, 2010).

Indeed, within the agricultural sciences, ethical concerns have a higher profile than they have had in the past. In most industrialized nations, there has been greater recognition of the need for including ethics and public policy issues in agricultural scientific education and research. Moreover, the challenges to the focus on production from within the agricultural sciences have increased receptivity to ethical and policy questions. For example, agronomy, once the province only of scientists concerned with enhancing annual yield, has become more fragmented as those concerned with sustainable agriculture and with molecular biology have entered the field. Thus, questions of the goals and practices of research, previously ignored, have moved closer to center stage (McIntyre et al., 2009). Indeed, a recent book talks of 'political agronomy' (Sumbert and Thompson, 2012).

The application of technologies to support productionist agricultural goals fosters what Thompson (2001) calls 'optimization' – the balancing of benefits and harms. However, in many cases, industrial companies reap the benefits (profits) while externalizing harms such as environmental degradation and food-borne illness. 'Technophilia' in agricultural production systems continues to shape organizational design and responses to emerging problems. This raises important ethical questions regarding unwavering loyalties to productionist ideologies, profitability, and technological solutions to problems. Short-term technological fixes may only temporarily reduce the symptoms of larger systemic problems in the food system.

Philosophers have also examined ethical aspects of the new agricultural biotechnologies. They note that in addition to nutritional qualities, food is always associated with cultural norms and rituals; hence, it occupies a special place with respect to ethics. Among the many issues of relevance is that of informed consent. In brief, it is often argued that consumers have the right to know what is in their food and to make decisions about what to eat on the basis of that information. From this vantage point, those nations that do not label biotechnologically altered foods violate important ethical norms. This appears to be poorly understood by the scientific community as evidenced by the recent decision by the American Association for the Advancement of Science to argue against such labeling.

In addition, critics of biotechnology have raised questions about the ethics of the use of animals in laboratory experiments, the development of herbicide-resistant crops, the use of bovine somatotropin to enhance milk production in dairy cows, the insertion of toxins from *Bacillus thuringiensis* to create insect resistance in maize and potatoes, and the establishment of intellectual property rights in plants and animals.

Future Directions

As environmental concerns have taken on greater significance for the general public, studies of agricultural science have begun to merge with environmental studies. For example, with growing concerns over climate change, there has been nascent interest in agricultural economics, history, sociology, and philosophy in examining its likely consequences for agriculture and agricultural research. Climate change is expected to shift cultivation patterns, crop and livestock populations, and farm practices as some regions become hotter, others become colder, and variability in weather increases. For example, Canadian prairie farmers are now shifting from wheat to maize production as longer, warmer summers permit production of maize with its much higher yields. In contrast, farmers in East Africa may shift from maize to more drought-tolerant sorghum production as rainfall variability increases. These shifts will require major changes in research programs and projects; they will also open new fields of research on agricultural research itself. In addition to research to facilitate climate change adaptation, scientists are also exploring ways to support climate change mitigation on agricultural lands through increasing carbon sequestration and reducing greenhouse gas emissions. This area of research is likely to expand and involve a variety of academic disciplines.

There is little evidence that the fragmentation that has plagued studies of the agricultural sciences in the past is coming to an end, although the entry of genetics and genomics into the plant and animal sciences has created new links with fields outside the traditional agricultural sciences. Nevertheless, disciplinary boundaries between the relevant academic fields remain relatively impermeable. Moreover, there are rigid institutional boundaries that still separate academic agricultural sciences from other fields of research. In particular, agricultural research and education tend to be found in specialized institutions, partly because of the specialized activities in which they engage, and partly because of the high cost of animal herds and experimental fields. Furthermore, those who study the

agricultural sciences often do so from within the confines of schools and colleges of agriculture. In some institutions, this puts restrictions on what topics are considered appropriate for research.

Abstract

Agriculture is predominant in primitive economies, but in industrial countries now it accounts for as little as 2% of economic activity. Malthusian worries have been forestalled as food has become very cheaper in real terms, though at the cost of dislocation of redundant farmers and economic problems for remaining agricultural producers. Productivity gains fueled by advances in technology have been the main driving force. Governments have promoted technological changes through investments in research, infrastructure, and institutions fostering market development, and have had to respond politically to situations of both food scarcity and surplus. In many instances, especially in developing countries, agriculture has been regulated and taxed in the pursuit of nonagricultural political interests, while in industrial countries agriculture is substantially subsidized. Agricultural economists have made progress in explaining many aspects of the interactions among technology, markets, farm incomes, and both domestic and international trade policies involving agricultural commodities and rural people, but many key determinants and trends remain only imperfectly understood.

Agriculture is distinguished from other sectors of the economy by virtue of its production processes (biological), its economic organization (on farms), and its products (food and fiber). The importance of these distinctions for economic analysis is not always evident, but they have been sufficient to make agricultural economics a separate subdiscipline of economics, with its own journals and professional organizations.

Agriculture's Primacy in Economic Development

In most of the world historically, and in much of the world today, the economics of agriculture is the economics of subsistence: the effort to wrest the food necessary for survival from productive but fickle resources. The essential economics concerns how individuals carry out such efforts and how families, villages, or other social entities organize their members for doing so. Economic development begins when agriculture generates production in excess of local requirements. Until the mid-nineteenth century the majority of the labor force in most countries of Europe was employed in agriculture. By the end of the twentieth century this percentage had been reduced to less than five in the richest countries. Similar patterns have emerged since 1950 in much of Latin America and Southeast Asia. Nonetheless, the World Bank (1997) estimates that 72% of the world's poor live in rural areas, and the prospects for economic development in agriculture remain a matter of worldwide concern.

A long-debated issue is whether agriculture is best viewed as an engine of growth, with investment in the sector an important source of economic progress or as an economically stagnant source of labor to be mobilized more productively elsewhere as the economy grows. 'Dual economy' models, in which agriculture is economically distinct from the nonagricultural sector, can accommodate both views, depending on how they treat mobility of labor and capital between the sectors, and the processes of technical change and investment in each. Such models can account for the observation of huge outmigration from agriculture together with wage and income levels in rural areas rising toward urban levels after falling behind in the early stages of industrialization. But they do not provide useful empirical guidance for fostering economic development in areas of the world where it still is the most needed. For those purposes, attention to microeconomic and sectoral detail is necessary. For reviews of economists' work on microlevel and aggregate questions, respectively, see Strauss and Duncan (1995) and Timmer (2002).

One of the most striking and still, to some extent, controversial finding about the economics of traditional agriculture is the wide extent to which farmers in the poorest circumstances in the least developed countries act consistently with basic microeconomic principles. They follow economic rationality in the sense of getting the most economic value possible with the resources at hand; but the innovation and investment that would generate economic growth are missing (Schultz, 1964). What is needed is to break out of the poor but efficient equilibrium by means of 'investment in high income streams,' mainly physical capital and improved production methods embodying new knowledge, and investment in human capital that would foster innovation in technology and effective adoption of innovations by farmers. Events such as the 'green revolution' that boosted wheat yields in India in the 1960s showed promising trends that have been sustained in many areas, but agriculture remained moribund through the 1990s in many places, notably in Africa and the former Soviet Union. Agricultural economics faces no more important task today than explaining and finding remedies for this stagnation.

Farms

Farms range from individuals working small plots of land with only primitive tools to huge commercial enterprises. Every operating farm embodies a solution to problems of product choice, production technique, mobilization of inputs, and marketing of output. Many of the choices to be made involve

nonmarket, household activities. Consequently, the economic analysis of farm households has become a major area of empirical investigation, calling upon developments in population and labor economics as well as the theory of the firm. Using these tools, agricultural economists have attempted to understand alternatives that have arisen in the economic organization of agriculture: family farms, cooperatives, plantations, corporate farming, state farms and so on (see for example Binswanger and Rosenzweig, 1986).

Organization of Production

A basic decision is whether to specialize or to diversify production among a number of products. The trend is strongly toward specialization. For example, 4.2 million US farms (78% of all farms) had chickens in 1950, but by 1997 specialization had gone so far that only 100 000 did (5% of all farms). Linked with specialization is the issue of economies of scale in farming. Throughout the developed economies there is a general tendency for farm size to increase over the last century. Data on farmers' costs indicate that a primary reason is economies of size. Yet there are many instances of very large farms failing. Collective farms in the former Soviet Union, employing thousands of workers on thousands of hectares, became paradigms of inefficiency. And in some developing country contexts there is evidence that small farms use their resources more efficiently than large ones. Optimal economic organization with respect to both specialization and scale depend on technical and institutional factors, most importantly the following.

Land Tenure

Land is a valuable asset and is necessary for farming. Yet farmers in many countries are poor. Institutional arrangements have evolved to enable farmers to cultivate and claim returns from land they do not own. The main ones are cash rental and sharecropping. Cash rental encounters several problems: the tenant may lack the means or access to credit for payment in advance, bears all the risks of crop failure or low prices, and has an incentive to use the land in ways that increase current output at the expense of future fertility of the land.

Under sharecropping, a common practice in both developing and industrial countries, the tenant pays after the harvest in the form of a fraction of the crop harvested. The share paid to the landlord varies widely, generally between one-fourth and one-half of the crop, depending on the quality of the land; the labor intensity of the crop; and the value of nonland inputs, if any, contributed by the landlord. In addition, the literature on optimal land contracting finds that shares depend on agency costs, production efficiency of tenants and landlords, and how risk averse each party is. Sharecropping divides production and price risk between landlord and tenant, and obviates the need for payment in advance. But it retains the principal–agent problem in lacking incentives to maintain future land quality, adds a disincentive for tenant effort in that the tenant receives only part of the tenant's marginal product, and adds an incentive for the tenant to underreport output and/or price received so as to reduce the rent paid. Such problems can be dealt with through monitoring, but that is costly. For a comprehensive review of the issues, see Deininger and Feder (2001).

The problems and costs of land rental increase the attractiveness of owner-operated farms, even if they have to be smaller. However, in many countries the institutions for private land ownership are not fully developed, nor are credit markets that would enable people with few initial assets to become landowners. In developed economies, land rental functions as a mechanism through which farmers can mobilize the land resources needed to achieve the least-cost scale of production. In the US in 1997, only 21% of cropland was on farms fully owned by their operators.

Agricultural Labor

About one-half the world's labor force works in agriculture, as either a farmer or a hired worker. (For data by country, see World Bank, *World Development Indicators*, 1998, **Table 1**.) Hired labor is common even on family farms. Hired farm laborers in both developing and industrial countries are among the least well paid and most economically precarious workers. Seasonal workers live under especially difficult conditions in that they often dwell in temporary quarters and are minorities or immigrants, sometimes with dubious legal status, which makes them ripe for exploitation. The plight of migrant workers in many countries has led to legislative and regulatory attempts to limit their numbers and improve their condition, and adds to a general sense that policies should be undertaken to enable landless laborers to gain access to land of their own and become farmers themselves. Nonetheless, hired labor remains a substantial fraction of the farm labor force in both rich and poor countries.

Credit and Input Markets

As agriculture modernizes, increased share of resources used are purchased seeds, fertilizers, chemicals, energy, and capital equipment. Farms that cannot invest become unable to compete effectively. If modern agriculture is to be undertaken by farmers other than those who already possess substantial assets, well functioning credit markets are essential. A major problem for agriculture in many countries is limited access to either purchased inputs or credit. Recent thought about credit markets has emphasized the problems that arise because of asymmetric information between lender and borrower leading to credit rationing or missing markets. If potentially productive loans do not get made, farmers and the rural economy are unable to grow to their potential. This reasoning has led many countries to provide subsidized credit to farmers, but the informational problems that cause market failure have not

Table 1 Annual costs and benefits of protection of agriculture in the EU, US, and Japan

	EU	*US*	*Japan*
Consumer costs due to higher prices	35	6	7
Taxpayer costs of subsidies	12	10	0
Gains to producers	31	12	12

been overcome with government involvement. In addition, the political provenance of these programs causes new problems.

Price Determination and Marketing

A recurrent complaint worldwide is farmers' lack of market power as compared to those who buy from and sell to them. Farmers typically have only a few alternative outlets for their products, and inputs they buy, but the extent of monopsony or monopoly power that results remains unclear. In many countries farmers have established marketing and purchasing cooperatives to increase their market power. In the United States, the first half of the twentieth century saw far-reaching governmental attempts to reduce the market power of meat packers, grain traders, railroad owners, food wholesalers and retailers, and banks through antitrust action and governmental regulatory agencies. The developed countries of the world are today replete with such efforts, and developing countries have followed suit as appeared technically and politically feasible. It is, nonetheless, unclear whether the economic problems of farmers have ever been principally attributable to their lack of market power, or that cooperatives or regulatory institutions have increased farm incomes appreciably.

Important recent developments in marketing involve contractual arrangements between farmers and processors that take some input provision and marketing decisions out of the hands of the farmer. Such changes have gone furthest in broiler chicken production in the United States, where the processor is an 'integrator' who supplies the baby chickens, feed, veterinary and other services, technical information, and perhaps credit. The farmer (or 'grower') receives a payment schedule, contracted for in advance, consisting of a fee per pound of chicken delivered that is adjusted for an efficiency indicator as compared to other growers (but not changes in the market for chicken) in return for the grower's effort in feeding and managing the flock and providing the properly equipped chicken house. Virtually all broilers in the country are now produced under some variant of this type of contract. Under these arrangements productivity indicators of output per unit input have grown far faster for broilers than for any other livestock product, and the US price per pound (live basis) of chicken relative to beef has declined from a ratio of 1.7 in 1940 to 0.5 in 1995. Similar production arrangements are increasingly prevalent for other meat animals.

Risk Management

In subsistence agriculture, crop failures or livestock deaths place the farmer at risk of starvation. In commercial agriculture, fixed costs of crops sown and interest on debt means that losing even a portion of the crop, or receiving low prices, can easily generate negative cash flow. Steps that a farmer can take to manage such risk include savings, diversification of enterprises, emergency borrowing, and purchase of hazard insurance against output risk, or some form of forward pricing against price risk. It remains open to question, however, how risk averse farmers are. Basic evidence that risk aversion is important is farmers' willingness to pay for insurance and their interest in pricing their output in advance. Observations that give pause about the importance of risk aversion are the many farmers who do not buy even subsidized crop insurance and who do not attempt to lock in a price for their output, even when contractual means for doing so are available. Nonetheless, evidence from developing countries suggests risk aversion of a magnitude that could readily impair farmers' willingness to invest in new production methods even when innovation would pay in expected value (see Moschini and Hennessy, 2001).

Production and Technology

The evolution of world agriculture over the long historical record is tied principally to changes in technology. Throughout the developed world, a large and sustained record of growth in agricultural productivity has been achieved. In the US, after 50 years of steady but unspectacular growth, agricultural productivity accelerated markedly after 1940 to a pace of about 2% annually, well above the rate of productivity growth in manufacturing. Moreover, that rate of growth has been maintained for 60 years, with little evidence of the productivity stagnation that plagued manufacturing in the 1970s and 1980s (**Figure 1**).

Economists have devoted much effort to measurement and analysis of productivity changes and farmers' decisions about input use. Nerlove (1958) developed a method of estimating both short-run and long-run output response to product prices. Empirical work using many variations on his approach over the last four decades has estimated generally small short-run effects of price. But in many cases the long-run effects are substantial. Griliches (1957a) provided the first fully developed economic analyses of the adoption of technology in his study of hybrid corn in the United States. Technical change and supply response have been merged in studies of 'induced innovation.' The chief causal factors identified in both supply and productivity growth have been advances in knowledge, improved input quality, infrastructure development, improved skills of farmers, and government policies. But the relative importance of these factors, even for the most-studied countries, still remains in doubt. Sunding and Zilberman (2001) is a comprehensive review of these factors.

Demand and Markets

The world's population tripled in the twentieth century from the two billion of 1900. Agricultural production grew sufficiently not only to feed an additional four billion people, but also to provide the average person with a substantially improved diet. And, the incidence of famine and starvation among the world's poor has been greatly reduced. This capability was not evident 200 years ago when Malthus formulated the proposition that the earth's limited production capacity, coupled with the propensity of population to grow whenever living standards rose above the subsistence level, meant the inevitability of increasing food scarcity (and worse) over the long term. One of the most notable facts about the twentieth century is the failure of Malthusian pessimism to materialize. Nonetheless, the plausibility of elements of this view – basically the fixity of natural resources in the face of

Figure 1 US farm total factor productivity index.

increasing population – is sufficient that the Malthusian worry resonates to the present day. It is therefore important to establish the circumstances under which food scarcity has ceased to be a salient social problem as well as the situations in which scarcity and famine remain a major cause of distress, and to understand why supply and demand have conspired to work out predominantly in the counter-Malthusian direction.

The single best indicator of food scarcity is the real price of staple commodities: cereals and other basic foods. Despite price spikes in wartime and the 1970s, the trend is for ever cheaper commodities. This trend primarily reflects lower real costs of production, a consequence of the productivity trends illustrated in Figure 1. While all acknowledge the uncertainty of any forecast, expert participants in a recent comprehensive assessment of world food prospects were in broad agreement that the trend of lower real prices of staple food commodities is most likely to continue in the twenty-first century (Islam, 1995).

An important factor in food demand is Engel's Law: the share of income spent on food decreases as consumers' incomes rise. The general rise of real incomes over the last century, coupled with the growth in agricultural productivity have meant an inexorable decline in agriculture's economic importance, and have been a source of chronic downward pressure on the economic returns of farmers. In many developing countries, especially former colonies whose economies became attuned to exports of primary products, declining commodity prices have been a key part of a bigger story of economic disappointment. Economic problems of farmers in both developing and industrial countries have kept agriculture firmly on the policy agenda almost everywhere.

Government and Agriculture

Political responses to problems of agriculture have generated a wide variety of government action. Four areas of activity warrant discussion: regulation of commodity markets, rural development policy, food policy, and resource and environmental policies.

Commodity Programs

Government intervention in agricultural commodity markets has been pervasive throughout recorded history. The primordial form of this intervention is taxation. With urbanization, implicit taxation of agriculture has arisen in many countries in the form of regulations intended to keep food prices from rising in times of scarcity. A sharp divide exists between the developing world, in which agricultural output is generally

taxed, and the industrial world, in which agriculture is generally subsidized. This pattern of taxation and subsidy has had the unfortunate consequence of encouraging overproduction in industrial countries and discouraging investment in agriculture in developing countries, many of which have a comparative advantage in agriculture. Contrary to what one might have expected, the share of world agricultural exports accounted for by industrial countries increased from 30% in 1961–63 to 48% in 1982–84, with a corresponding decrease in developing countries (World Bank, 1986: p. 10).

The protection of agriculture in industrial countries harm agriculture in developing countries, and also each industrial country's protection makes it more costly for other industrial countries to maintain protection. The Common Agricultural Policy (CAP), created with the establishment of the European Economic Community in 1958, is notorious in this respect. The main policy instruments of the CAP go back to Britain's Corn Laws of the ninetieth century tariffs that maintain protection against imports by rising when world prices fall ('variable levies') and export subsidies to dispose of domestic surplus production (see Ritson and Harvey, 1997). In the first two decades of its existence the CAP moved its members from being net importers to net exporters of wheat, rice, beef, and poultry meat. Other grain-growing countries that also desired to maintain support prices for their producers introduced or accelerated export promotion and subsidy programs of their own, notably the US Export Enhancement Program of the 1980s. The subsidy competition exacerbated a worldwide decline in commodity prices in the 1980s, increasing the costs of US 'deficiency payments' that made up the difference between legislated 'target' prices and market prices for grains. This in turn triggered massive acreage-idling programs; in 1985–87 about a fourth of US grain-growing land was idled.

The World Bank (1986: p. 121) assessed the annual costs and benefits of agricultural protection in the largest Organisation for Economic Co-operation and Development countries as shown in **Table 1** (in billions of dollars).

Note that the costs to consumers and taxpayers together far outweigh the producer (more specifically, landowner) gains, with the sum for the EU, US, and Japan being a net welfare loss of US$25 billion.

Accurate measurement of these gains and losses is difficult, but virtually all analysts estimate substantial net losses in the industrial countries and to producers in developing countries during most of the post–World War II period, and accelerating losses in the 1980s. This situation provided the stimulus for agricultural policies, after lengthy and contentious negotiations in 1986–93, to be subjected to internationally agreed disciplines that began to be implemented in 1995 under the auspices of the World Trade Organization.

Individual countries have also initiated moves toward less market distorting intervention in the commodity markets in the 1990s. In the developing world, substantive steps in deregulating commodity markets were taken in many countries of Latin America and East Asia; and in Africa many countries reformed and/or abolished marketing boards and related interventions. Most radical of all, beginning in the late 1980s (and before the breakup of the Soviet sphere in 1989), a renunciation of state control of farm enterprises occurred in China and throughout Eastern Europe and the former USSR. But the reforms have as yet achieved nothing near complete liberalization in developed, developing, or transition economies, with the exception of New Zealand.

Rural Development Policy

A broader agenda of governments in promoting economic growth in agriculture and rural areas has more widespread support. Economists have generally concluded that provision of certain public goods and infrastructure investment has been crucial in the economic development of agriculture and that the absence or deficiency of such governmental support is an obstacle, perhaps an insuperable obstacle, to economic growth in agriculture in countries where it has not yet occurred. The World Bank has taken a strong role in urging market liberalization in developing countries and at the same time proposing a broad program of public investment in pursuit of rural development (World Bank, 1997).

Legal Institutions

The most fundamental economic service the State can provide is a system of law governing property and contracts, and protection from lawbreakers. This requirement is not of course peculiar to agriculture, but must be mentioned because legal institutions in rural areas are not weak in many transition and poor economies, especially regarding use and control of farmland and water resources. In industrial countries, too, these institutions have to evolve in response to changes in technical and social realities, most notably, in the 1990s, the establishment of property rights and contractual procedures that bear on innovations in biotechnology.

Agricultural Research, Extension, and Education

Even with well-established institutions fostering private sector research and development, research and information dissemination are likely candidates for public funding, and have long been so funded in many countries. Griliches (1957b) pioneered methods of estimating the costs and benefits of publicly supported research. Since then hundreds of studies in both developing and industrial countries have replicated his finding of extraordinarily high rates of return to public investment in research and the dissemination of knowledge through extension activities (Evenson, 2001).

Since the work of Schultz (1964: Chapter 12) investment in schooling has been seen as a cornerstone of what is needed to improve the economic well-being of farm people, and of increasing agricultural productivity. Solid empirical evidence of the effects of education on farming has been hard to come by, however. Even so, there is widespread support for improved education in rural areas, recently with particular attention to the education of women. Evidence is strong that schooling improves peoples' earning capacity, so it is a promising remedy for rural poverty even if it causes its recipients to leave agriculture.

Rural Infrastructure

Governments in industrial countries have made major investments in roads, railways, shipping channels, and ports to provide remote areas with cheaper access to markets. Lack

of such infrastructure is a major impediment to agricultural development in many parts of the world today. But we have nothing like the studies of returns to research to provide evidence on the rate of return to such investments, and the anecdotal evidence is replete with failure as well as success stories. Even more controversy swirls around investments in water projects. Irrigation was important in facilitating fertilizer response to the new grain varieties that triggered the green revolution of the 1960s, and is essential for opening up arid areas for production. At the same time, dams and irrigation works have been heavily criticized in recent years. Many cases of low or negative returns to large investments have been cited, and the environmental costs of lost habitat for endangered species and reduced water quality have been emphasized. Recent work by agricultural economists has emphasized improving institutions for water pricing and assignment of use rights more than further investment in large projects.

Food Policy

A chief source of governmental discrimination against agriculture in developing countries is a desire to keep food prices low for urban consumers. In industrial countries, too, attempts have been made via price ceilings and export restrictions to keep a lid on food prices in periods when they have risen sharply, as occurred in the commodity boom of the 1970s. More important ongoing policies address the regulation of food quality and safety, food assistance for poor people at risk of undernutrition, and famine relief. Chemical residues on food and the use of genetically modified organisms in agriculture were especially contentious issues in the 1990s.

An important bifurcation of countries today is between those in which food security remains a pressing national issue and those in which assurance of an adequate diet is the problem of only a small minority of the population. International food aid has become a permanent policy in industrial countries, particularly famine relief. Mobilization of funds for such efforts can be difficult except in cases of well-publicized disasters, but the more salient analytical issues have involved the nature of famines and the effectiveness of alternative approaches to remedy the suffering and death they cause. It has become apparent that in most famines the problem is not so much physical unavailability of food as a lack of income with which to acquire food. This may seem a distinction without a difference but the implications are profound for the most effective administration of aid. It has been argued, for example, that it can be counterproductive simply to ship food products to be disbursed by local governments. The undesired result is distribution that is too often negligible to those who most need the goods, and at the same time a depression of commodity prices and hence of the incomes of local farmers who produce goods that compete on the same market as goods brought in but lack income for an overall adequate diet. Generally, international donors have to be careful not to take actions harmful to local coping mechanisms, which in many poor areas are well developed from long and bitter experiences. See Barrett (2002) for a comprehensive review.

Resource and Environmental Policy

The relationships between agriculture and water quality, soil and other resource depletion, wildlife habitat, and chemical contamination have become front-burner policy issues in industrial countries, and are beginning to get attention in developing countries. A difference from the regulation of industrial polluters is that agricultural pollution sources are typically small, scattered, and difficult to monitor. Certain agricultural pesticides have been banned in industrial countries, but reasonably good substitutes have so far been available. Nonintensive uses of erodible or otherwise environmentally sensitive lands have been fostered in the US and Europe by paying farmers to undertake recommended practices.

Nonpolluting and resource saving practices for developing countries have been promoted by international agencies as conducive to 'sustainability' of their productive resources. However, countries have resisted some of these ideas, such as restraints on opening up new land or eschewing large new dams and irrigation projects. The debate is difficult because of a lack of documentation in which the loss of forests and conversion of other lands to agricultural purposes at rates now occurring is a mistake that will come to be regretted. In Europe and North America, an issue that has become prominent in recent decades is the conversion of farmland out of agriculture and into residential and commercial use in suburban areas, not so much out of concern about lost food production but rather because of the loss of open space and other community amenities that farming provides. Land use regulation and agricultural subsidies of various kinds have been introduced, most extensively in Europe.

Agricultural Politics

Why has agriculture been widely discriminated against in developing countries, and supported in developed countries? Evidence that the explanation is not country specific is that countries that have grown sufficiently rich to move from the developing to the developed category, largely in East Asia, have moved from taxing agriculture to subsidizing it. A large body of recent work has attempted to explain the strength and resilience of farmers' political clout in the richest countries, especially in Western Europe, Japan, and the North America. It is particularly notable in that this strength has been maintained even as the farm population has declined from one-fourth to one-half of the total population 50 years ago to 2–10% today. It is also instructive that some commodities are protected much more heavily than others within each country. Many reasonable hypotheses on these and related matters have been advanced, generally linked to interest group lobbying and democratic politics. Knowing more about agricultural politics is important because a governmental role is essential in many aspects of agricultural and rural development, yet governmental action in commodity support programs, trade restrictions, and other regulatory areas have imposed large social costs that are notably resistant to reform. The goal is governmental institutions that provide the services that contribute to sustainable development and that reform wasteful policies. The goal is far from being realized.

Abstract

Agroecology has been defined as the marriage of agriculture and ecology, and has evolved to embrace whole food systems including production, economics, environmental impacts, and social implications of change. This field now broadly addresses the *ecology* of food systems. Agroecology has developed in response to awareness of declining resource availability and negative impacts of conventional chemical agriculture. With people's growing concern of importance of whole systems research and development, agroecology has now an emerging focus on food production and food systems, and is a vital engine for conceptualizing and implementing responsible agricultural change.

Introduction

Agroecology grew from concerns about long-term sustainability of food production, as many people recognized diminishing supplies of fossil fuels, fresh water, phosphorus, and other key resources and the impacts of these changes on agriculture. Another current reality is the loss of land with productive soils for food production, as soils are increasingly degraded, topsoil is lost, fields accumulate salts, and large areas are appropriated for other human pursuits. Future scarcities of fossil fuel energy and irrigation water for agriculture are accelerating due to demands from other sectors, but less well known is the change in land use to purposes other than food production. In addition to land dedicated to biofuel production instead of food, thousands of hectares are converted each year to industrial use, housing, roads, and other urban infrastructure (Olson and Lyson, 1999). The challenge of producing much more food per hectare by mid-twenty-first century to feed a growing world population will require an intensification of production on available farmland, as well as methods to rehabilitate land that is degraded or lost. We must solve major problems related to food storage and distribution, access to food for poor people, and changes in diets to make everyone more healthy.

Green revolution technologies have provided impressive gains in food production. The higher yields achieved over the second half of the twentieth century have contributed to lower food prices and improved human well-being in many parts of the world. They could only be sustained if research reveals more efficient ways to use scarce resources and achieve resilience in the face of looming changes in climate, especially greater incidence of major storm events that interrupt industrial monoculture agricultural practices. Increased yields of crops have indeed been one of the 'modern miracles' from application of practical science in agriculture, but limitations are on the horizon (Hazell, 2002).

Major yield increases have been achieved by higher crop genetic production potential, applications of high levels of chemical fertilizers and pesticides, and spread of irrigated farming practices. To achieve high yields, farmers mainly use practices that depend on heavy reliance on inputs from off the farm, and that increasingly are based on specialization and large areas in monoculture crops. In more fertile areas, this technology-driven change to an industrial model of farming has produced global grain harvests that have almost kept up with increasing human population and demand for food. Yet there is serious concern that we are reaching the genetic plateaus for yields of major cereal crops, e.g., maize, wheat, and rice (Grassini et al., 2013), limiting future potential for increased yields of these essential crops. Advances through science have contributed to confidence that new technologies will always overcome resource shortages, and have created an attitude of complacency that diverts thinking from resource scarcity and limits to growth. Thoughtful evaluation of resource investment in ever more intensive and expensive technologies and reliance on a singular industrial strategy in agriculture raises concerns about food sustainability. Agroecology addresses these concerns and provides a platform for seeking alternatives.

There are growing concerns with how to counter the often negative environmental impacts of intensive use of fertilizers and pesticides that are integral to industrial technologies. There is further concern that current improved technologies have reached only those farmers with adequate financial resources to access the fruits of science. In reality nearly half the food available today globally is produced by small farmers with traditional methods, and this is unlikely to change in the near future (IAASTD, 2008). This report from the United Nations included contributions of 500 scientists over a period of 5 years, who concluded that agroecological methods that improve intensive systems used by small farmers can provide one solution to food challenges for many rural families. Agroecology combines methods from biophysical and social sciences to look at how and where food is produced, how it follows a chain of transformations to reach the consumer, and how this contributes to healthy diets and human well-being.

Development experts also recognize that many present challenges are not due to inadequate food production, but rather result from economic and political priorities. Current inequities in food availability within countries and regions suggest that our present system is not meeting human needs. Conservative estimates are that 30–40% of food produced does not reach the table due to losses in harvest, storage, processing, and the marketing system as well as being wasted in consumers'

homes (IMechE, 2013). In developing countries there is often inadequate or faulty storage capacity, while in developed countries much food is discarded because of blemishes or excessive caution about food safety. Agroecology promotes inquiry into these questions that can only be answered through analysis of the whole food system including who has access to food and who benefits. Therefore, not only agronomic and ecological, but also many economic and social factors have to be taken into account to develop the whole human production and consumption system – from 'field to the plate.' Appropriate analyses include socioeconomic factors that are closely integrated into the biophysical processes involved in agriculture, clearly a human activity system.

Background

Holistic systems planning has been central to the thinking of farmers for centuries, as they make decisions based on available land and production resources, balance land use for crops, livestock, and meeting needs of the family while producing additional food for sale or barter. History of the term 'agroecology' to describe complexity in agricultural systems and their interactions with the environment was described by Gliessman (2007 and prior edition) and Wezel and Soldat (2009). Broadening use of this term to describe the ecology of food systems – including production, processing, marketing, food consumption – is a recent event (Francis et al., 2003). Wezel et al. (2009) have further summarized and categorized agroecology as a science, as a set of practices, and as a movement. Multiple interpretations and diverse uses of the term agroecology complicate understanding and communication. What is agreed is the importance of current and potential production of food, economics of systems that make them profitable for farmers, environmental impacts of this human activity system that puts at risk quantity and quality of food production in the long term, and social consequences of different types of agricultural systems and how they influence food security and food sovereignty (Francis et al., 2013).

Science of Agroecology

Growing appreciation of the complexity of challenges facing those who produce, process, and market food has led to new approaches to study whole systems. Many of the early advocates of linking ecology with agriculture came from the sciences, and first use of the term was by Bensin (1935, and prior citations) in U.S.A. who talked about ecology related to commercial agriculture. The German ecologist Tischler (1950) used agroecology to discuss problems in pest management and soil biology, and recognized the importance of interactions in complex systems. Altieri (1983) and Gliessman (2007) have pursued the science theme and popularized agroecology as an integral part of the science discourse.

Early application of the concepts of integrated systems was adopted in plant protection and Integrated Pest Management (IPM), in large part a response to Rachel Carson's landmark book *Silent Spring* (Carson, 1964). Development has been especially active in California, U.S.A., with IPM described as a complex method designed to reduce chemical application and improve the environment (http://www.ipm.ucdavis.edu). Definitions of IPM include ecosystem approaches to crop protection that combine multiple management strategies that minimize the use of chemical pesticides (Abrol, 2014). Researchers in organic farming systems are now providing science-based recommendations for improving production (Francis, 2009). One unique application of ecological principles is the research on perennial polycultures, with the objective of creating a multispecies system that produces cereals and legumes for human food as well as forage for grazing livestock (Jackson, 1980). Such systems are designed to produce their own soil fertility and protect against pest damage through functional biodiversity.

Acceptance of agroecology has been less enthusiastic in economics. Most production cost analysis at the farm level concerns short-term expenses and benefits, with focus on cash flow and need to maintain a profitable whole farm operation to stay in business. On a larger scale, we recognize that macroeconomic analyses using national data and contemporary methods that examine consequences of systems in the short-term are inadequate to understand large inequities in current food distribution and availability within a country, for example. Such measures as Gross National Product also disguise substantial differences in distribution of income, and thus access to food, and human welfare. The simplistic and inadequate measurement methods used today to assess economic conditions compel those in research and development to examine new models and metrics in the food system, and suggest that more complex indices could be developed to adequately measure and report economics in terms of human welfare. The emerging perspectives and methods used in agroecology research and education provide useful approaches to look at whole food systems. It should be noted that agroecology is still used in a narrow sense by many scientists to describe applications of ecology in agriculture. Research has provided the foundation for practices described in the next section.

Agroecological Practices

Practical applications of ecological principles include many ways of introducing both spatial and temporal biodiversity into design of cropping and farming systems. When animal traction was important to land preparation, cultivation, and harvest there was extensive planting of hay crops and pastures in small fields that provided species, farm-scale, and landscape diversity. With mechanization, removal of livestock from most farms, and wide planting of a few crops in monoculture, there is far less diversity at all levels of spatial scale and limited use of rotations in present industrial systems. Moving toward greater diversity with some practices that more closely mimic natural ecosystems is one strategy toward generating more fertile soils and protecting against pests without using chemicals.

Crop rotations of cereals and legumes, summer annuals with winter annuals, and perennial species with annual crops all provide diversity in types of root systems, lengths of growing cycle, and residues from crops that contribute to more efficient

nutrient and water use as well as soil fertility. Maize–soybean rotation is a common practice in the U.S. Midwest, but one that has lost favor as price of maize for multiple uses has increased. Likewise, low production costs and ready market for export have caused a large conversion to continuous soybean production in the Pampas Region of Argentina. More complex multiyear rotations that include these important summer crops with winter wheat or other cereals, sunflower, and alfalfa can introduce greater diversity and resilience to cropping systems. A traditional cow/calf grazing system (4–6 years) in rotation with annual crops (3–4 years) provided enough soil nutrients and plant protection to keep this sequence profitable and sustainable for many years in Argentina (Rotolo et al., 2007), although this has been replaced by short-term rotations or continuous cropping of species suitable for processing and export. Studies of more complex rotation systems show that they can be more efficient in resource use and more sustainable in energy terms, and provide examples that can support policies to return to diverse cropping and crop/animal systems (Altieri, 2009).

Agroforestry, sometimes called permaculture, is another system of practices that combines annual crops with perennial plantings and includes a strategy that will maximize internal cycling of nutrients within the system, and in some cases also incorporation of animals (Mollison, 1988). Multiple cropping systems (intercropping) are also valuable strategies used by smallholder farmers throughout tropical and temperate regions (Francis, 1986; Wezel et al., 2014). These combine several crops in strips (strip cropping, relay cropping, alley cropping) or in random plantings that include species diversity and different intensities of interspecific competition in the field. Biodiverse systems may include as many as 15–20 species in the same field during a year, for example, in the humid forest zone of Nigeria or the subtemperate south of Taiwan. Although these systems are not convenient in large fields or with industrial-size equipment, they can be highly productive if managed well, and these systems currently produce a substantial proportion of the world's food (IAASTD, 2008).

Agroecology as Movement

Largely in Latin America, agroecology has been seen as a social movement with the goal of transforming agriculture from an industrial and large-scale exploitation, highly dependent on fossil fuels and outside resources, to a more sustainable strategy that builds on human ingenuity and renewable resources that are internal to the farm. One key person in this movement has been Miguel Altieri, who was a founder of the Latin American Scientific Society of Agroecology (SOCLA), and also an active author who has linked science with practices and organized movements in sustainable agriculture (e.g., Altieri, 2009). This movement is promoted internationally by Via Campesina, an organization that publicizes the efficiencies of small-scale agriculture and promotes a social agenda of peasants' rights to land and a goal of food sovereignty (http://viacampesina.org/en/). Brazil has been at the forefront of grassroots activities by small farmers, and one of the early advocates José Lutzenberger (1976) was Special Secretary for the Environment to the President of Brazil from 1990 to 1992.

Agroecology in Teaching

Although the principles of ecology seem logical to apply in agriculture to reduce pesticide use, and to find biological methods to generate or liberate the nutrients needed to maintain crop yields, there has been slow acceptance of the term and academic courses in most agricultural universities. This may be due in part to its association with organic and biodynamic agriculture, or alternative agriculture, or to the promotion of agroecology as a social movement by activist groups perceived as a challenge to mainstream institutions. The strength of agroecology as a valuable practical direction to maintain production and profitability, reduce negative environmental impacts, and meet social goals such as food sovereignty is found in its transdisciplinary and holistic approach to identifying challenges and solutions (Lieblein et al., 2012). As a result, agroecology curricula became more popular in the last decade of the twentieth century at universities in Europe and in the U.S.A.

Recent Changes in Agriculture

Agriculture continues to evolve to meet new economic, political, and social challenges that are part of larger changes in the global society and environment. Design of production systems today is impacted by growing costs of fossil fuel based inputs, by rapidly changing technologies, by climate change, and by emerging power of consumers in food systems. Scarcity of fossil fuels and other key production inputs such as phosphorus is shaping a research agenda to make agriculture more efficient in use of limited resources. Genetic improvement for nitrogen and water use efficiency is high on the research agenda. Agroecologists approach this challenge by seeking systems less dependent on nonrenewable inputs and design of strategies that are based on local and renewable resources such as sun and rainfall, nitrogen fixed by legumes, management of pests using crop diversity, and integration of biodiversity. New technologies such as equipment guidance systems and precision application of fertilizers and chemicals are now used to reduce inputs and put them where they are most effective. Agroecologists propose this location-specific management through application of agroecological practices, better knowledge and observation of fields, and alternatives to purchased inputs. Transgenic crop varieties are now widely used in some parts of the world, but their safety and economic returns are the subject of continuing debate.

Climate variability is increasing, with greater frequency of major disruptive storm events and change of rainfall amounts and patterns that are beyond control of the farmer. Highly diverse agroecological systems help to build in resilience in farming systems by having several crops at different stages of development, and multiple potential uses for grain and forage that can buffer unfavorable weather events. Including a range of crops and animals in the system builds on integration efficiencies of enterprises, such as livestock that consume crop residues, and provides a range of products for the market to buffer changes in prices as one useful strategy. Direct marketing schemes such as farmers markets, farm sales shops, community supported agriculture, and pick-your-own operations provide

direct links with consumers and raise awareness of how and where food is grown. Growing demands for organic foods and locally produced products act as a countercurrent to the global food economy, and people are becoming more concerned about animal welfare as well as labor conditions where food is produced. These are among the changes that are evaluated in agroecology, in a quest to make food systems and supplies more transparent and encourage consumers to make informed choices about their food. The perspectives and methods of agroecology are increasingly recognized as leading to creative solutions for improving small farm agriculture (IAASTD, 2008) by taking these methods and scaling them up to impact national food production and human well-being (Ecumenical Advocacy Council, 2012).

Conclusions

Agroecology has emerged in the early years of the twenty-first century as an organizing philosophy that is guiding research and education in holistic and integrated agricultural and food systems. While recognizing the technological advances and production successes of the green revolution that brought more food and better well-being to many disadvantaged people, there have been unintended environmental consequences of wide-scale use of chemical fertilizers and pesticides. To produce food and adequate diet for 9 billion people, requires new thinking and innovative strategies for positive change in agriculture.

Scientists and development specialists are now recognizing that adequate food for all people depends on a wide array of social and economic challenges to be overcome. These include use of food crops to produce biofuels rather than changes in current systems to make them more energy efficient, loss of food in the chain from harvest in the field to consumption at home, and pervasive inequities in control of production resources and adequate incomes to allow many poor people to access food. The complexity of these challenges can best be evaluated and systems improved through transdisciplinary understanding and responsible action by public, private, and nongovernmental organizations working together. Agroecology as the 'ecology of food systems' provides a platform for study of agriculture and food systems from production to the consumer, also considering the importance of food distribution, diets, and healthy food. The major goal is moving toward agricultural systems that depend on renewable resources, conserve biodiversity, and that can be sustainable for the long term. In a globally connected world, the importance of local systems and specific solutions for unique places will be part of the future of agriculture and food systems.

Abstract

The AIDS epidemic of the 1980s shone a dark light on the assumptions of contemporary biomedicine. The world was confronted with a disease which it did not understand, could not treat, and which often attacked previously healthy young men. It had echoes of the great plagues of medieval times that decimated the cities of Europe and Asia. Theories abounded about its cause, until it was discovered that a previously unknown retrovirus instigated the destruction of human immune cells. What was particularly challenging about AIDS was its impact on society that extended beyond the usual concerns of biological medicine. Western medicine prided itself on its research methodology and development of new instruments and techniques to study organic processes. What medicine did not do particularly well at the time was to attend to the psychological, social, political, and ethical dimensions of the illness. The onslaught of AIDS altered all of that and forced the biomedical world to broaden its conception of illness and consider elements that went beyond the physical basis of pathology. Every aspect of this illness compelled medicine to ask new questions, challenge old assumptions, and build new collaborative relations with the patients. This article deals with the history of the HIV infection, its clinical manifestations and course, and issues in understanding its virology and immunology. It considers contemporary treatment options and the psychological and economic issues that they generate. It also discusses the neuropsychiatric complications of HIV disease, the psychosocial stressors accompanying the infection, and ethical and policy issues regarding diagnosis and treatment, as well as special problems confronted by minorities, women, care givers and their families, and people living with HIV from resource-limited countries.

With AIDS, the world was confronted with a disease that it did not understand, could not treat, and that often attacked previously healthy young men. Theories abounded about its cause until it was discovered that a newly emerged retrovirus instigated the destruction of human immune cells. Western medical science had recently been comfortable in the belief that infectious diseases were coming under scientific control and that the major health problems of the age lay in the understanding and treatment of chronic diseases and those of aging.

What was particularly challenging about AIDS was that its impact on society extended beyond the usual concerns of biological medicine. Medical science was at the time enjoying groundbreaking discoveries in the arenas of genetics and cellular and molecular biology. It was coming to better understand the mechanisms of diseases and was devising innovative methods of diagnosis and treatment. What medicine did not do particularly well at the time was to attend the psychological, social, political, and ethical dimensions of illness. AIDS altered that, and forced the biomedical world to broaden its conception of illness and consider elements that went beyond the physical basis of pathology. The old authoritarian models of the doctor–patient relationship are gradually being replaced by a process where patients are empowered to gather more information about their condition, play a greater role in making treatment decisions, and become more self-directive in maintaining their health. All of this has taken place in an environment where new discoveries about virology, immunology, and treatment strategies are rapidly occurring.

The story of human immunodeficiency virus (HIV) infection and its culmination in the disease that is called AIDS starts in the USA in the early 1980s (CDC, 1981). Surprised physicians treating young gay men noted that they were falling ill and dying in increasing numbers. There was no clear diagnostic reason for this phenomenon, and a variety of guesses was ventured as to the cause. The number of reported incidents of this strange illness began to increase. Soon it was discovered that patients receiving transfusions for hemophilia and also intravenous drug users were being reported with this disease. Reports began coming in from Africa documenting that heterosexual men and women were likewise falling ill in alarming numbers. It became evident that the primary site of the pathology was the destruction of an important component of the immune system, the CD4 helper T cells that are responsible for mounting a critical defense against infectious agents (Cooper et al., 2013). As a result of the loss of immune competency, an array of 'opportunistic' infections attacked the infected individuals and instigated a wide array of illnesses that infiltrated many body organs, chiefly the lungs and central nervous system (CNS).

Since the first cases in 1980s, around 75 million people have become infected with HIV globally. Statistics also revealed that there were 35.3 million people living with HIV in 2012 (UNAIDS, 2013). AIDS became the leading cause of death globally in the past decades. With the increased awareness and more people accessing treatment over the years, people living with HIV began to live longer; new HIV infection and AIDS-related deaths have also decreased by over 30% since its peak in the new millennium.

The Etiology, Immunology, and Clinical Pathology of HIV/AIDS

There has been some confusion in the public mind about the use of the meaning of the concepts of HIV and AIDS. The term 'HIV' refers to a person's infection with HIV. This virus can be

transported from one person to another through the exchange of certain body fluids (blood, semen, or vaginal discharge). It enters certain immune cells in the body and can progressively destroy them over time. The presence of this virus can be detected by testing antibody titers that reveal the body's response to its presence. A person can be HIV+ and be asymptomatic for long periods of time, or show only mild flu-like symptoms after acquiring the virus, a condition known as a *seroconversion* illness. This virus belongs to a *retrovirus* group called *cytopathic lentiviruses*. These are RNA-based viruses that convert their RNA to DNA and insert that into a cell's genetic pool through a process called *reverse transcription*; they have high mutation rate because of the high error-reading in the *RNA transcriptase*, an enzyme that transcribes viral RNA to viral DNA (Domingo et al., 1996; Roberts et al., 1988).

There are two types of HIV that have been shown to cause AIDS in humans: HIV-1 and HIV-2 (Peeters et al., 2014). These viruses share similar molecular structures and cause similar pathological disruptions. Currently, HIV-1 causes the majority of cases of AIDS throughout the world, while HIV-2 is found mostly in Africa. There are many different subtypes among the HIV-1 strain. These viruses can rapidly change their molecular structure within the body, making them difficult for the immune system to destroy. The mutability of these viruses also makes them difficult targets for preventive immunization strategies.

The term *AIDS* refers to a critical stage of the HIV infection when a large number of CD4 helper T lymphocytes have been destroyed, and the body is not able to mount an effective immune defense against secondary opportunistic pathogens or the toxic effects of HIV itself (Gong, 1984). The first symptomatic signs of immune breakdown may not occur for a number of years after the acquisition of the virus; latency might vary between 4 and 10 years. HIV can provoke diseases that involve the lymph nodes, lungs, brain, kidneys, and the abdominal cavity. There is no universal sequence of clinical symptoms, but the most frequent presentation can include enlarged lymph glands, pneumonia-like symptoms, decline in blood counts, and fungal infections, as well as diarrhea, weight loss, bacterial infections, fatigue, and disorders of the central nervous system. The Centers for Disease Control in 1993 compiled a list of conditions that defined AIDS. This included such infections as toxoplasmosis of the brain, tuberculosis, Kaposi's sarcoma, candidiasis infection of the esophagus, cervical cancer, cytomegalovirus (CMV) retinitis with loss of vision, and progressive multifocal leukoencephalopathy (PML), a viral infection that destroys white matter in the brain. Conditions on the list include opportunistic infections, or diseases that would otherwise not occur in the presence of a healthy immune system.

In order to best understand this devastating disease and its treatment, it is important to understand the relationship of the virus to the immune system. HIV is known as a retrovirus, which means that it can alter the flow of genetic information within a cell. It uses the enzyme *reverse transcriptase* for utilizing viral RNA as a template for producing viral DNA (Roberts et al., 1988). In most cells, DNA produces RNA as a genetic messenger. The sequence of infection after the entry of the virus through exchange of body fluids is the following: (1) the virus attaches to a host immune cell using the CD4 and CCR5 receptors (**Figure 1**); (2) the virus sheds its molecular coat and once it enters the cell, it begins the processes of reverse transcription; (3) viral DNA is integrated into the host cell, causing transcription and translation of the viral genetic code into viral protein, and inducing the host cell into producing more copies of the invading virus; (4) the newly formed viruses are released into the bloodstream, with the death of the host cell and the reinvasion of new immune host cells.

The helper T cells have the CD4 surface receptor that has a high affinity for the HIV surface protein gp120 (Wilen et al., 2012). However, HIV can attach to other cells including macrophages and monocytes (other immune cells), as well as cells in the intestines, uterine cervix, and Langerhans cells of the skin. Researchers have found that chemicals called cytokines also play a significant role in facilitating viral invasion. Interestingly, there are certain mutant strains of cytokine genes that actually prevent the entry of HIV into the target CD4 cell. Studies found that C–C chemokine receptor type 5 (CCR5) delta-32 homozygosity, which leads to a truncated protein, has a protective effect against HIV infection in that the virus cannot

Figure 1 HIV envelope protein gp120 loop attaches to the CD4 receptor and the coreceptor (CCR5 or CXCR4), and while another viral protein gp41 fuses with the cell membrane in order to initiate viral entry into the host cell.
Source: US National Institutes of Health – National Institute of Allergy and Infectious Diseases.

bind to the truncated receptor (Taborda-Vanegas et al., 2011; Estrada-Aguirre et al., 2013). The presence of these genes in certain people may explain why some individuals remain resistant to HIV infection despite repeated exposure to virally loaded body fluids and why some people show slower rates of disease progression. There is also evidence that a patient from Berlin who received stem cell transplantation with this mutation has been cured of HIV (Allers et al., 2011).

Not all infected cells immediately produce new viral copies that destroy the cell and infect many others. Some cells may remain dormant or latent without producing new viral copies. There may be adjuvant factors that convert latent infected cells into ones that produce viral copies. It is speculated that coexisting infections with their additional antigen load may have a facilitating effect, as may certain drugs, possibly stress, fatigue, and so on. Anything that reduces immune competency may become a cofactor. Many individuals who are infected try to find ways to strengthen the immune system. These attempts may include meditation, exercise, herbs, dietary supplements, prayer, and support groups. Whether these have any long-lasting ameliorative effects is uncertain, but they may give the person a greater sense of self-maintenance and control over a devastating illness.

Issues of Testing for HIV and Stages of the Infection

When HIV infection was first recognized in the early 1980s, it was most prevalent among young men who had sex with other men and were living in large metropolitan cities. Prevention programs and the availability of tests for the infection have significantly decreased the rate of new HIV cases among this population. The major routes of infection with HIV have been shown to be through fluid-exchanging sexual behavior; use of HIV-contaminated needles; from mother to infant during pregnancy, delivery, or breast feeding; and through HIV-contaminated blood products passed during transfusions. The development of accurate testing procedures for the infection became important both to assist in the diagnosis of the disease and to protect the nation's blood supply.

Various means of testing for the presence of HIV or its effects have been developed since the discovery of the disease (Crews et al., 2009). The virus can be cultured directly from the blood, but the most efficient means of diagnosis has come from detecting antibodies to the virus. Such testing can determine whether the body has come into contact with the virus and has mounted an immune defense. However, antibody testing can produce both false positive and negative results, and cannot be used during the window period (usually 3–6 months) where the level of antibodies is too low to be detected. Most tests take a few days to receive results, but more rapid same-day tests are available. The usual procedure is for the patient (blood, urine, or saliva sample) to be tested first using an enzyme-linked immunosorbent assay (ELISA), which is very reactive to HIV antibodies. An HIV RNA test allowed early detection within 2 weeks after a suspected infection, therefore could be utilized during the window period of HIV antibody test. A positive result on the first test must be replicated in a western blot antibody test before a diagnosis can be made. It has a high level of specificity for detecting protein antigens of HIV. Rapid point-of-care HIV tests have also been developed to deliver the health care service to resource-limited area (Glynn et al., 2014; Chamie et al., 2014).

Although there are reasonably accurate and fast methods of testing for HIV, not all people who suspect that they have been exposed to the virus seek testing, and not all who do arrange for it early in the progress of the infection. There are a variety of reasons why this is so, some people are simply not aware of the risks of infection and the procedures of arranging for testing. Others have been properly educated, but because of lack of perceived risk, stigma, denial, fear of the outcome, and concern about loss of privacy and public exposure, avoid learning if they have been infected (Ances et al., 2008).

Often when a person has received a reliable diagnosis of HIV infection, they experience a variety of negative psychological responses. They can become anxious, and or depressed, may feel guilt about their past behavior, and are worried about physical deterioration and eventual death. If they have observed friends experience the progress of the disease, they may have frightening images of what may happen to them. Suicidal thoughts are often present immediately after a diagnosis is made and the patient may become sensitive to any physical symptoms. It is vital that such persons receive comprehensive, sensitive, and accurate medical and mental health care upon receiving news of a positive test. Many people at this point in the illness feel isolated, shamed, and unable to talk about their fears and questions. Since the onset of the epidemic, many outstanding clinical and community programs providing vital information and emotional support have been established. Since significant advances in therapies have been developed, with a marked increase in survival rates, early detection and humane medical and psychological interventions are essential for all.

The Clinical and Immunological Progression of the Illness

The finding of a positive antibody test for HIV does not predict an inevitable disease course for all people. Some people exhibit only mild symptoms initially and then remain totally asymptomatic throughout their lifetime. Others demonstrate severe symptoms shortly after the virus is detected and others show no sign of illness for 8–10 years after being diagnosed as positive. AIDS, now termed HIV disease, has uncertain symptoms, long quiescent periods for many, and in the past often lead to a devastating end state.

There are many reasons to explain this variability. Some may have a genetic resistance to the virus, a robust (innate and adaptive) immune system and have been exposed to a less virulent strain of the virus (Kaul et al., 2005). For others, diagnosis may occur long after they were exposed to the virus and their immune system may be severely compromised.

When told that they may develop HIV disease, people face many uncertainties, complex medical and lifestyle decisions, and the need to adapt to changing medical conditions throughout their life. These decisions involve trusting communications with health care workers, friends and family, social support systems, and work associates. For some, the complexity of these decisions may prove overwhelming, and

they may make many poor health and lifestyle decisions. For others, the illness may reactivate existing psychiatric problems or create new neuropsychological symptoms. Indeed, one of the most provocative complications of the disease is the emergence of HIV-related cognitive disabilities (Almeida, 2013).

As noted earlier, the harm caused by HIV is instigated by its entry into the CD4 helper T lymphocyte and the cells subsequent capture of HIV genetic material along with the use of the host cell's machinery to produce many new viral copies. When a full-fledged infection is in progress, millions of new viral particles can be found in the human bloodstream. This causes a drop in the number of CD4 cells, which usually have a level of at least 800 cells/cubic millimetre of blood. Counts below 500 are considered serious and below 200 cells/mm^3 will set the stage for dangerous opportunistic infections (Young et al., 2012). Periodically testing the concentration of CD4 cells has been an important means of measuring and predicting the course of the disease. More recently, tests have been developed to measure the viral load directly in the bloodstream and body fluids. These sensitive tests are considered a most reliable measure of the progress of the infection.

The Progression of the Illness

Acute Infection or Seroconversion

Following the entrance into the immune cells, there is a dramatic drop in CD4 counts and usually the onset of symptoms that can resemble flu or mononucleosis. These can include fever, fatigue, enlarged lymph glands, headaches, rashes, and muscle aches. These symptoms usually resolve in few weeks, as the immune system resists the viral spread. It does so by triggering CD8 cytotoxic cell responses that destroy infected cells and by stimulating an antibody response to the virus (Demers et al., 2013). This reaction binds and removes many HIV particles from the blood.

Viral Latency

These body defenses reduce the viral load but rarely eliminate the virus from the body. In many cases, there tend to be an equilibrium established between the immune defense and the viral level. This so-called 'set point' can be quite different from patient to patient. Whether a patient will become seriously symptomatic depends upon the balance between viral activity and immune competence. When viral activity gains the upper hand over immune defense, serious symptoms will occur. Depending upon when the diagnosis was first made, the set point can vary from 4 to 10 years. Some patients, called 'non-progressors,' may never show serious symptoms and maintain good CD4 levels.

HIV Disease or AIDS

Individuals who have compromised CD4 counts, have a bout of opportunistic infections, and yet be asymptomatic thereafter. Once the CD4 count drops below 200 cells//mm^3, people usually develop complications of HIV disease. The immune system is no longer able to contain the viral spread, and organisms that it usually can control begin producing dangerous infections. Most common are pneumocystis carinii, pneumonia, and toxoplasmosis. However, many other organisms can also be activated and cause multiple organ damage. When the brain is affected in the end stages of the disease, delirium, dementia, and a variety of motor impairments can occur. In other countries where this disease is common, there may be a different array of opportunistic infections found. In places such as Haiti and Africa, one sees more candida infections and crytococcal meningitis. Intestinal disorders with diarrhea and wasting are also common. Both abroad and in the USA, tuberculosis associated with HIV has at times become a major issue.

The Treatment of HIV Infections

The combined antiretroviral therapy (cART) has been highly beneficial for people living with HIV, delaying disease progression and improving quality of life significantly. The introduction of cART has contributed to a sharp decline in the mortality related to HIV infection; however, it needs to be taken for life. The cART does not cure HIV and people living with HIV can still progress to develop HIV-associated neurocognitive disorders (Passaes and Saez-Cirion, 2014). Despite various public and private funded HIV prevention and treatment initiatives, such as the Bill & Melinda Gates Foundation Fund, the Global Fund, and the Ryan White Comprehensive AIDS Resources Emergency (CARE) Act, a significant proportion of people still have restricted access to the ART due to financial limitations. This has created serious national and international concerns about creating a two-class partition concerning distribution and access to these medications. Such questions will inevitably arise as new, expensive, and sophisticated treatments are developed to treat other chronic conditions.

Since the introduction of these new treatment regimes, the death rate from AIDS has dropped steadily since the peak in 2005, and the number of HIV-related hospitalizations has been significantly reduced (UNAIDS, 2013). This was accomplished through a more detailed understanding of the molecular activity of the virus as it enters a human cell. To date, there are 28 Food and Drug Administration (FDA) approved drugs for the treatment of HIV infection in five different classes, each targeting a specific molecular mechanism. These are (1) nucleoside-analog reverse transcriptase inhibitors, (2) non-nucleoside-analog reverse transcriptase inhibitors, (3) integrase inhibitors, (4) protease inhibitors, and (5) fusion/entry inhibitors (Kinch and Patridge, 2014). The new classes of drugs operate either by blocking viral replication or by inhibiting the HIV reverse transcriptase and protease. The original drug against HIV was developed in 1987 and was called *Zidovudine* (*AZT*) (Kinch and Patridge, 2014). This drug is a nucleoside-analog reverse transcriptase inhibitor, functions by preventing the completion of the viral DNA strand in the human cell. Later, non-nucleoside reverse transcriptase inhibitors were developed which also inhibited retroviral activity. The protease inhibitors were subsequently developed, which prevents the division of newly produced HIV proteins. The fusion/entry inhibitors prevent viral entry by blocking the HIV-binding coreceptors CCR5 and CXCR4. More recently, a new class of

integrase inhibitors was introduced to block the action of integrase, a HIV enzyme that facilitate the integration of viral genome into host cell. The usual prescription is for a combination of two or more classes of drugs.

The development of these powerful drugs is important because research has shown that the HIV reproduction is robust early in the disease, but remains stable because of the immune response that produces high numbers of CD4 cells. A strong initial response of CD4 cells facilitates the body's subsequent production of a CD4 subset that reacts selectively to HIV. Medical research has determined that the level of the viral load in the body is highly correlated with ultimate prognosis. If the viral level can drop to an almost undetectable level, the likelihood of developing opportunistic infections and other complications of HIV disease declines (Dembek et al., 2012).

Important as the development of these effective medications have been, they still further complicate the lives of people living with HIV and create a myriad of complex decisions for them. Previously, the medications must be taken on a rigorous schedule and sometimes in extremely large doses. Failure to maintain the timing of a dosage of the drugs may result in their being ineffective, and possibly producing viral resistance. Even when taken correctly, the drugs may not be effective, leading to disappointment.

The recent development of fixed-dose drug combinations (FDCs) represent a major advancement in cART, where the 'cocktail' regimen (up to 16 pills daily) has been simplified to the new once daily, single-tablet regimen (STR) (Aldir et al., 2014). This novel treatment therapy has been found to significantly enhance treatment adherence among people living with HIV, therefore improving their quality of life. With the great benefits, the STR has now been approved and adopted in many countries as the first-line treatment for people living with HIV.

Although a vast improvement in drug development and financial assistance is available, other difficulties such as negative side effects remain challenging. These may encompass anemia, neuropathy, headache, diarrhea, rashes, and hepatitis. The complexity of this medication approach requires a close collaboration between the treating physician and the patient. It underscores the necessity of having the patient being an active participant in his or her treatment.

The latest discovery of the 'Berlin patient' who was allegedly found cured of HIV, followed by two patients from Boston who underwent a similar situation, initiated research searching for HIV cure (Cannon et al., 2014). These patients received a stem cell transplant with CCR5 delta-32 homozygosity mutation from the donors, as part of their cancer treatment, and were later found to have non-detectable viral load. These findings marked the beginning of a new era of biomedical research for treatment and prevention of HIV infection, at the same time provided people living with HIV with a hope for cure.

Neuropsychiatric and Psychosocial Issues

Although HIV infection can cause a wide number of dangerous medical complications, none are more feared by people living with HIV than the neuropsychiatric disorders. HIV can cause damage to the CNS itself and open the door to a myriad of opportunistic brain infections. The possible end-stage of delirium and dementia with loss of personality and body function control is a grim vision of their future.

HIV infection can not only introduce a number of CNS disorders, but it can also cause the reactivation of previous psychiatric illness (Almeida, 2013). There are a great number of people living with who also have a previous psychiatric history. Often these people may be less capable of taking reasonable precautions with regard to unsafe sex and intravenous drug use, rendering themselves vulnerable to infection.

HIV invasion of the CNS has previously been found in more than 50% of people who are HIV + but asymptomatic, and over 90% on autopsy of all AIDS patients showed evidence of neuropathology (Gray et al., 1996). More recently in the era of cART, 78% of postmortem brain samples from individuals with advanced HIV disease showed some degree of neuropathology, which is associated with HIV-associated neurocognitive disorders (HAND) (Everall et al., 2009). These brain abnormalities include inflammation such as HIV encephalitis (HIVE), white matter and subcortical damage, as well as neurodegeneration such as synaptodendritic damage and neuronal loss (Gendelman et al., 2012). Inevitably, patients with involvement of the CNS show symptoms of cognitive impairment, movement problems, and behavioral difficulties. These difficulties may include a change in personality, withdrawal and apathy, inappropriate emotional responses, sharp mood swings, mania or suicidal impulses, and hallucinations. Often the brain involvement leads to an inability of the patient to carry out activities of daily living and requires home assistance. There is belief among some clinicians that early diagnosis and vigorous drug treatment can delay or even prevent later HIV-associated dementia (HAD). This will depend upon the extent of CNS damage existing at the time of initiation of treatment. Lithium and neuroleptic medications have been used to systematically treat people who become manic or agitated (Schifitto et al., 2009). There is also evidence that lithium may be neuroprotective against HIV and could potentially be used in conjunction with cART to improve HIV-associated neurocognitive impairment (Letendre et al., 2006; Ances et al., 2008). The exact means by which the HIV causes damage in the CNS is not certain. There are two possible routes of HIV damage in the CNS: a direct insult where neurotoxicity is triggered by HIV viral protein such as gp120, tat, and nef; while an indirect damage can occur when macrophages and microglia release pro-inflammatory cytokines in response to viral infection and prolonged oxidative stress (Kaul et al., 2005).

Although the presentations of AIDS-related opportunistic infections and tumors have become uncommon due to the efficiency of cART, the milder HAND remain prevalent, potentially due to people living longer with HIV infection (Chan and Brew, 2014). The variation in the severity of HAND between people living with HIV could potentially be due to different CNS penetration properties of drugs administered, or genetic protective factors mentioned earlier (Eisfeld et al., 2013). Nevertheless, treatment with high CNS penetrating antiretroviral (ARV) does not necessarily predict a better outcome of HAND as revealed by a study that reported neurotoxicity features of ARV (Akay et al., 2012).

Both the organic and social stresses of HIV/AIDS are associated with the emergence of psychological distress and

psychiatric symptoms. The most common psychological disorder associated with HIV infection is an adjustment disorder with features of anxiety and depression. Major depression is often observed among people living with HIV (Fellows et al., 2013). This is most common among those with a previous history of depression and those who are isolated and have little social support. A feeling of hopelessness and lack of personal control over the development of the disease is found among these depressed patients. People living with HIV disease experience, during the course of their illness, a variety of losses and other stresses that increase their vulnerability to psychiatric disorders. In the past, these included loss of employment, death or illness of friends, disengagement of family members, financial losses, loss of sexual partners, abandonment of future goals, reduction of physical function, and failing cognitive abilities. Fortunately, with the successful HIV treatment these significant losses are not as common today. Although there are a generation of people living with HIV who survived the pre-cART era that are still coping with the detrimental effect of those historic losses on their lives today.

The occurrence of depression, anxiety, somatization disorders, suicidal ideation, and substance abuse can be traced to the reaction to such losses, or the fear of them. Such psychological distress may by itself compromise the immune system. With the advancement in the field of pharmacology, there is an array of antidepressants and antianxiety medications available today to help manage these conditions. Positive mental attributes acquired through therapy, support groups, prayer, and so on, may also modulate the psychological pain of the patient and help to improve the quality of daily living. Research has not yet determined whether developing more adequate coping mechanisms and enhanced self-esteem will effectively alter the immunological course of the illness.

Like so much else in this disorder, there is no common psychological pathway that all patients follow. Their previous psychiatric history, adaptive responses to the virus, social support, financial resources, access to good medical care, response to medication, will all play a role in helping people living with HIV achieve a positive mental equilibrium. Supportive therapy can help patients deal with fear, uncertainty, and a sense of self-recrimination. Such help can occur in a professional setting, through community groups, religious counseling, and in a variety of other innovative venues. The important consideration is to help people to feel that they are not worthless, socially shunned, or without something valuable to contribute to friends and society.

Policy and Ethical Issues

This epidemic has emphatically raised the question of what is the responsibility of governments, pharmaceutical companies, and insurance plans for protecting and treating people of very limited financial means. HIV disease or AIDS involves populations of individuals who are often out of the spotlight of public attention or who have been morally condemned because of certain behavior characteristics. The most striking example of an ignored population is the many millions of heterosexual individuals who have fallen ill with AIDS in Africa. This disease has disrupted families, created national economic disaster (particularly in agriculture), and has overtaxed the medical resources of extremely poor countries. Yet in the richest industrial and technological countries in the world, there is little concern or knowledge about the problems on this continent. The ethical responsibility for providing the benefits of modern medicine and pharmacology to people in a distant and largely unknown continent is now beginning to emerge in the public's awareness.

In Europe, Australia and other developed countries, people living with HIV are entitled to free or subsidized access to cART at the point of health care delivery. The USA's record in responding to the needs of minorities and underprivileged people with the infection even in its own country is not a cause for optimism. Medical care and treatment for people with AIDS is expensive and as a chronic disease, its costs mount over time. Infected people often lose their insurance, are no longer able to work, and exhaust their financial resources quickly. Yet at the beginning of the twenty-first century, there is at best a patchwork of initiatives to finance the development of drugs and make them available to those in need. Currently available funding of treatment is only sufficient for a small proportion of people living with HIV globally; numerous people are still in need of treatment and care, especially those in the resource-limited areas. Contemporary policy must also take into account the many women and, at times, their children who are infected with HIV. They require many additional social and educational services to deal with their medical and social problems. Attention must also be given to the special needs of adolescents who are at greater risk for contracting this disease.

Compounding the problems of money are issues of protecting both the privacy of people with HIV infection, while also safeguarding the public's health. Generally, it has been felt that well-conceived educational programs can play a major role in both prevention and helping infected persons to make ethical decisions about disclosing their condition to others. Related to this question are issues regarding blood bank testing, protection of health care workers, and disclosure to prospective and current sexual partners.

In the USA, diseases that are sexually transmitted have become a metaphor for troubling issues about 'moral' behavior. It raises questions about the values of the society, parents' control over the behavior of their children, and the images that are conveyed by the media to the public. Among some groups, sexually transmitted diseases are seen as a punishment for immoral behavior. Much of the public's response to AIDS, even after two decades of familiarity with the disease, is shaped not by its medical and biological characteristics, but by US social and cultural attitudes toward the behaviors associated with contracting the illness. People's willingness to help those who are afflicted is molded by their social perspectives. If the public disapproves of the people who have contracted this disease, they are reluctant to provide the medical care, drugs, shelter, and the social support that they need.

The HIV/AIDS epidemic has also raised questions about the right to access to medications that have not yet met Food and Drug Administration standards for testing and release to the public. Should drugs that have not yet proven their safety be given to people who might otherwise die?

What has emerged, however, is the belief that patients and their advocates have a right to be at the table where scientific and public health decisions are being made. Patients must participate in decisions regarding the initiation and termination of treatment, rights of privacy concerning their condition, informed consent, and access to new forms of treatment. Of particularly interest is the AIDS Coalition to Unleash Power (ACT UP), an international group of advocates devoted to promote and protect the well-being of people living with HIV and ultimately end the disease. The notable achievements of the group in the early days include the significant price reduction of Zidovudine manufactured by Burroughs Wellcome, and the ban of placebo use in HIV treatment trials.

The lessons learned in understanding AIDS are reshaping views of the roles of doctor, patient, family, and community. Hopefully, such new knowledge will provide a more humane and comprehensive attitude for the care of patients with all diseases. Illness is not an event that happens in just one person's body. Its consequences are part of the social fabric. Ethical consideration, as well as advances in biological expertise, must inform future policy and health care decisions.

Abstract

Hans Albert is one of the most influential philosophers of science and social philosophy in the German-speaking world. In the 1960s, he participated in the German 'positivist dispute' on the same side as Karl Popper against T.W. Adorno and Jürgen Habermas, helping to reestablish analytic thinking in German social philosophy. He defended Max Weber's postulate that scientific statements should be free of personal values against its critics. In ethics, Albert has argued for a noncognitivist position. As an outspoken proponent of naturalism, he has repeatedly challenged theology on the ground of its lack of adherence to the rules of science.

Hans Albert, born on 8 February 1921, is one of the most influential philosophers of science and social philosophy in the German-speaking world. He is considered to be one of the main proponents of critical rationalism, a branch of analytic philosophy founded by Karl Popper during his debates with philosophers of the Vienna Circle.

Albert has identified three principal features of the philosophical position he represents: (1) *logical fallibilism*, which is the conviction that all human attempts at problem solving are fundamentally fallible and may need to be revised in the light of new information; (2) *methodological rationalism*, also called the method of critical examination, according to which two steps can be distinguished in any attempt at problem solving: the development of new proposals for solving problems based on experience, imagination, and intuition, and then testing based on reality; and finally, (3) *critical realism*, which includes the belief that although knowledge of reality is always fallible, nevertheless, in principle, it is possible.

Biography

After attending high school in Cologne and serving in the army during the Second World War, Albert commenced his studies as an economics major in the winter semester of 1946 at the Faculty of Social Sciences and Economics of the University of Cologne. The intellectual climate at the university was marked by ideological disillusionment and fervid study; the German sociologist Helmut Schelsky later referred to these students as the *skeptical generation*. Albert, who had already been intensively interested in Oswald Spengler while he was in high school, studied numerous philosophical works in an unsystematic manner, in addition to his pensum of business and economics literature. The thesis for his Diploma was supervised by the sociologist Leopold von Wiese, who also agreed to supervise his PhD studies.

Even at this early age, the very strong influence of Max Weber can be seen, which shaped Albert's thinking for the rest of his life. He summarized his experiences in his own words as follows:

> Soon I was filled with a deep sense of mistrust against a science where – in contrast to Max Weber's principle of objectivity – hidden value judgments seemed to abound and beyond that the real validity of postulated scientific laws hardly seemed to be regarded as a major problem. This discipline seemed to be the perfect example of an ideology, much in the sense which the sociologist Theodor Geiger later characterized as pseudo-scientific statements lacking all empirical basis. Since no one presented any contrary arguments in discussions either inside and outside the university, which were likely to dispel my concerns, I felt that my critical perspective was reinforced again and again.
>
> Albert, 1977/1984: 10

In the summer of 1952, Albert became a postdoc in the Department of Social Policy at the Research Institute for Social and Administrative Sciences, headed by Gerhard Weisser, of the University of Cologne. Weisser was a Kantian from the Leonhard Nelson School, who was intensively interested in fundamental questions. At the Weisser Institute, Albert became acquainted with the works of modern logic and logical positivism, particularly with those of Victor Kraft, whose theories on objectivity and conventionalism Albert soon learned to appreciate. Albert sympathized with the Vienna Circle philosophers, retaining however an existential approach in ethics questions.

In 1955, Albert submitted the dissertation for his Habilitation (second PhD), entitled 'National Economy as Sociology of Commercial Relationships.' The goals of the dissertation were, first, a critical analysis of the modern 'pure' Economics from the perspective of the philosophy of science, and second, the development of the foundations for sociologically oriented empirical Economics, which traces economic processes to the behavior of individuals in certain social roles, thereby taking institutions in society into account. At first, the faculty refused to accept the dissertation because, on the one hand, the novel epistemological approach raised concerns and, on the other, for political reasons, some faculty members suspected Albert of secretly sympathizing with Marxism. Albert was finally able to get his habilitation in 1957 for his other work on the subject of social policy. He taught as an associate professor until 1963 when he was given a new chair in Mannheim for 'sociology and philosophy of science.' He remained there until he became emeritus professor in 1989.

At the suggestion of Ernst Topitsch, Albert started visiting the Alpbach European Forum in 1955. It was there that he got to know, among others, Paul Feyerabend, Alf Ross, and

(in 1958) Karl Popper. Based on his impressions from this meeting, he wrote the comprehensive article 'The critical rationalism of Karl Raimund Popper,' which was published in 1960 in the *Archiv für Rechts-und Sozialphilosophie*. The article anticipated many of the elements present in Albert's main work, the *Treatise on Critical Reason*. In Alpbach, he met in 1956 Margarete von Pacher, whom he married in the winter of 1957. Today Hans Albert lives in Heidelberg.

The German 'Positivist Dispute'

In October 1961, the German Sociological Association (DGS) held a conference in Tübingen to discuss the methodological conflict which had been simmering for some time between empirical sociologists, represented in particular by René König and the Frankfurt School, which was influenced by Marxist ideas. The two main speakers were Karl Popper, who presented a paper on the logic of the social sciences, and T.W. Adorno, who was asked to be the cospeaker. The two rival speakers, both of whom had been forced to emigrate by the Nazis, treated each other graciously despite their significant ideological differences. The dispute became more acerbic when Habermas published an article in 1963, in which he portrayed Popper as a naive positivist (which was the philosophical movement that Popper had distanced himself from in the paper he had presented in Tübingen). Albert replied, which provoked a new rebuttal by Habermas. These and other articles were later published together and repeatedly reissued as an anthology entitled *The Positivist Dispute in German Sociology*.

The positivist dispute quickly created a sensation which went far beyond the simple methodological issues. Many people regarded it as a political dispute between critical rationalism and the Frankfurt school, whereby one side took up the banner of Max Weber and the other the banner of Karl Marx. Today, with 50 years hindsight, one can say that the critical rationalists won on all the major issues. Even the former protagonists in the dispute, particularly Jürgen Habermas, have moved away from their previous neo-Marxist positions, and in substance (but not in vocabulary or style of expression) have moved closer to the positions held by critical rationalism. As its final result, the positivist dispute caused a realignment of the German social sciences. It led to a rehabilitation of analytic approaches in social philosophy, which had been banished from the German-speaking world by the Nazis, as well as to a clear convergence with the scientific style of the Anglo-American world.

Criticism of Whether It Is Possible to Prove an Ultimate Truth: The 'Ultimate Justification Problem'

In 1968 in his book *Treatise on Critical Reason*, Albert grappled with the classic problem of justification, i.e., whether it is possible to know something for certain, much in the style of Descartes' search for a foundation for knowledge. Albert's answer was that it is impossible to get a justification which is certain. In order to make his position plausible, he introduced the so-called *Münchhausen Trilemma*, which, to this day, is still closely associated with the name Hans Albert:

> If one requires a justification for everything, one must also require a justification for the knowledge used to obtain the justification. This leads to a situation where there are three alternatives, all of which appear unacceptable. This is a trilemma, which I want to call the *Münchhausen Trilemma*, because the problem we seek to solve is analogous to the problem Münchhausen faced. Namely, one only has a choice between:
>
> 1. an infinite regression, which appears because of the necessity to go even further back, but is not practically feasible and does not, therefore, provide a certain foundation;
> 2. a logical circle in the deduction, which is caused by the fact that one, in the need to found, falls back on statements which had already appeared before as requiring a foundation, and which circle does not lead to any certain foundation either; and finally,
> 3. a break of searching at a certain point, which indeed appears principally feasible, but would mean a random suspension of the principle of sufficient reason.
>
> Albert, 1968/1991: 15, translation from German slightly modified

Reference to the Münchhausen Trilemma is supposed to show that a certain 'final' justification is not possible. This idea reflects the logical fallibilism which according to Albert should be observed not only in theoretical philosophy, but also in social philosophy and legal philosophy. The trilemma is certainly not limited to deductive conclusions, but rather it is relevant whenever for the justification of one thesis, a different thesis has to be cited.

The Relationship Between Natural Sciences and Social Sciences and the Problem of Objectivity

The three pillars of critical rationalism – namely logical fallibilism, the idea of critical examination, and the approach of critical realism – do apply not only in the natural sciences but also in the social sciences and humanities. Albert rejects the Humanities' claims for autonomy, as have been traditionally expressed in Germany, for example by the Hermeneutics around Gadamer, or the Frankfurt School around Adorno, Horkheimer, and Habermas. The standard model of scientific explanation, which goes all the way back to Carl Gustav Hempel, is, according to Albert, applicable in the social sciences and humanities. Advocates of a special status for the social sciences and humanities argue that human language and other human artifacts cannot be explained, but only *understood*. In contrast, Albert pointed out that 'explaining' and 'understanding' take place in different contexts, namely understanding in the context of discovery and explaining in the context of justification. In his later works, Albert modified this position, arguing there could be a 'technology of understanding,' like hermeneutics in the eighteenth century. Albert emphasizes the methodological unity of the social sciences, which links him with a clear commitment to a naturalistic understanding of the world.

In particular, Weber's *Postulate of Objectivity* is applicable, according to Albert, just as much in the natural sciences as it is

in the social sciences and humanities. This means that researchers must distinguish clearly between facts and their own particular political or moral judgments, so as not to deceive the public about the status of statements made.

The *Werturteilsstrei*t (value judgment dispute), which took place in the 1920s between Max Weber and his critics, has played a prominent role to this day in the German social sciences. The positivist dispute, mentioned above, can be interpreted as a renewal of the earlier value judgment dispute. An understanding of these conflicts is complicated, however, by the fact that to a certain extent, widely different issues have been confounded. In order to remedy that, Albert distinguished the following subquestions:

1. The *logical problem* concerns the question of what meaning to give value judgments. What is important here is primarily the question of what is the difference between statements of fact and value judgments.
2. The *methodological problem* concerns the issue of whether value judgments are necessary in Science, or expressed another way, what goals would make it necessary to use value judgments in Science.
3. The *definitional problem* is whether a language system which includes value judgments can be regarded as 'scientific.'
4. Finally, there is the moral problem whether scientists, not only as private persons but also as teachers in science, can or should express value judgments. This problem is called the *Problem of Kathederwertung* (lectern value judgment) in German.

Statements of fact like 'the picture is 100 years old' and value judgments like 'the picture is beautiful' possess of course the same surface grammar, but differ significantly in their logical content. Albert follows here the results of the Anglo-Saxon metaethics (Stevenson, Ayer), which he adopted quite early and helped spread in the German language area. Statements of fact describe reality. They can be true or false. In contrast, value judgments express, in addition to their descriptive contents, also an assessment, which means a personal opinion of the person making the value judgment. This personal opinion can be political, moral, or, as the example above shows, aesthetic in nature.

The methodological problem of whether value judgments are necessary in the social sciences, Albert answers firstly, by differentiating three questions, namely (1) Can value judgments be the object of social science research and predictions? (2) To what extent do scientific propositions in the social sciences contain such value judgments? (3) To what extent do such value judgments form the basis for scientific propositions in the social sciences? Albert's answer to the first question is unreservedly 'yes.' It is one of the main tasks of the social sciences to examine value judgments. Albert answers the second question, following Max Weber, saying that the social sciences should limit themselves to making available knowledge. It is not the task of the social sciences to make political or moral value judgments. Albert answers the third question, about the extent to which value judgments form a basis for social science research, with affirmation. Even the decision to conduct a scientific enquiry contains a value judgment. The same is true for the area of the research, the research subject, and the methodology chosen.

In summary, Albert felt that it was unnecessary or even dangerous to confound factual statements from the social sciences with moral or political value judgments, because such statements would confuse the general public, which would not be able to distinguish which were facts and which opinions. An academic activity, in which hidden value judgments and other prejudices abound, should not be referred to as a science. It was right so that Albert considered it to be misguided for university professors to mix together factual statements and value judgments when conducting their lectures, without drawing the audiences' attention to what they were doing.

Albert's rigorous defense of the postulate of scientific value freedom has often been criticized as 'conservative,' particularly by representatives of the Frankfurt School such as Adorno or Habermas, who in the late 1960 and 1970s frequently combined academic research with political postulates from neo-Marxist ideology. This led quickly to criticism. The philosopher Martina Plümacher wrote:

> The idea that Science could explain 'facts' and political positions like demands for the fulfillment of basic human needs, but should not preemt political or cultural decisions as a substitute for open public discussions …is fundamentally a radically democratic idea, the roots of which lie in the convictions of the Enlightenment, that all human beings are fundamentally able to think and to come to reasonable, responsible decisions. It reflects a belief in rational solutions to conflicts using democratic institutions and assumes the existence of active political participation by citizens in a democratic state.
>
> Plümacher, 1996: 145

National Economy and Law

National Economy (today usually referred to as Economics) and Law possess in Germany a common disciplinary background in the subject 'Political Economy,' even though the subjects have diverged significantly since the mid-twentieth century. Economics has always worked mainly with idealized assumptions about reality and sees itself as a theory of rational behavior. Mathematical models continue to be used in place of empiric research.

Early on, Albert criticized the methodology employed in Economics as '*model platonism*,' advocating that Economics makes use of the research results of empirical sociology to a far-greater extent than ever before. An overly mathematical Economics was in danger of immunizing itself from real experience.

Albert also expressed opinions on the subject of Law several times. Within the methodology of continental legal science, the view prevails that jurisprudence is a *dogmatic normative* and *hermeneutic* discipline, which means that it assumes that the law is found in statutes, and it attempts, by interpreting the statutes, to derive solutions to resolve concrete legal disputes. In several works, Albert subjected continental jurisprudence's understanding of itself to detailed criticism. Subsequently he made a case to Rudolf von Jhering for a teleological or 'socially technological' understanding of the law. American legal realists, especially Karl Llewellyn, advocated a very similar model. Statutes and the interpretation of statutes are then a means to achieve certain agreed-upon goals.

This model seems obvious today for statute law: Parliament passes laws in order to achieve its legislative goals. The utility of a particular statute, then, lies in its ability to achieve the goals intended by the legislature. Thus, an empirical, truly scientific criterion is used which allows scientifically supported statements to be made about the suitability of statute laws to achieve certain specified purposes.

The situation is very similar, according to Albert, with respect to legal practice. A lawyer works out potential interpretations of a statute, which may be more or less suitable, to achieve the legislative objectives of the statute. When choosing the 'right' construction of a statute, empirical knowledge plays a role. In more recent legal discourse, the term 'result oriented' judicial decision making has come into use.

Ethics

A question, which is one of the most renowned traditional problems in Ethics, is whether moral judgments are either a question of *cognition* or a question of *decision making*. At first glance, statements like 'Murder is wrong' or 'Thou shalt not murder' seem to reflect an established legal or moral order. Whether, for example, the rule exists in the social morality of England or Germany, that one should not murder, would then be a question of cognition. Nevertheless, the question of whether the precept 'Thou shalt not murder' is right or wrong is generally not understood with reference to a particular system of social morality. Rather, the question which is asked is whether it is right or wrong in general, regardless of whether it occurs in one system of social morality or another.

Moral and social philosophers have found two types of answers to questions of this kind: *Cognitivists* are of the opinion that we can recognize what is morally right or wrong. This position presumes that for mankind what is right or wrong has been previously established in some way; for example, the same way that reality determines our responses to questions of fact. Prominent cognitivist ethical systems include Platonist values, as found in Plato's works, traditional natural law, and Kant's moral philosophy. Such positions, however, have always met with criticism. Skeptics consider them to be refuted. They prefer noncognitivist moral systems, in which norms and values have not been prescribed for mankind, but rather came into existence as the product of human decision making. The most important proponents today of this so-called noncognitivism come either from the logical empiricist or from existential philosophy camps. A single statement by Wittgenstein characterizes both of these movements: "We feel that even if all possible scientific questions are answered, the problems in our lives remain untouched" (Ludwig Wittgenstein, *Tractatus logico-philosophicus*, statement 6.52).

Hans Albert takes what is essentially a noncognitivist position in this dispute, but he considers the radical differentiation between cognition and decision making to be exaggerated. Of course ultimate justification is in his opinion impossible not only in the area of factual knowledge but also in the normative area. The Münchhausen Trilemma is applicable in both areas. On the other hand, our knowledge already contains numerous determinations and therefore decisions, for example, with respect to the selection of objects of enquiry and fixing the meaning of the vocabulary used. Decision is therefore also an aspect of our experience.

According to Albert, the idea of critical examination, and the methodologies derived from it of construction and criticism, can also be successfully applied to normative questions. The *unity of reason* links all kinds of human problem solving. Value axioms and normative systems based on these axioms can be analyzed, for instance, for their logical consistency. A second approach which links cognition and decision making is the identification of the factual consequences resulting from the acceptance of certain values and norms. These examples show that the idea is incorrect that in the field of morality no possibility exists for rational assessment.

Morality is not invented at the drawing board. Rather, all people are born into a certain social morality, the values and standards of which appear to them as natural. Albert refers illustratively to *value Platonism* of the natural orientation of the world. Moral philosophy has the task of critically examining established morals:

> For a critical moral philosophy its main task is not to provide the morality prevailing at any time with dubious justifications, in order to anchor it more firmly in the consciousness of the people and the social order. Its job is rather to critically examine that morality, uncovering its weaknesses, and developing ways to improve it.
>
> Albert, 1968/1991: 90

A fundamental principle of any critical moral philosophy is that it is impossible to derive norms from statements of fact (or vice versa). In philosophy, this principle is typically referred to as 'Humes' Law.' Whoever nevertheless purports to derive a 'should' from an 'is,' or an 'is' from a 'should,' is committing a logical error which is usually referred to as the 'naturalistic fallacy.'

Albert proposed the so-called *bridge principles*, in order to overcome the logical barrier between statements of fact and values/norms. In this way, normative statements would be made accessible to evidence-based criticism. The first bridge principle he calls the principle 'should implies can.' Based on this principle, norms which require the impossible can be criticized, and, under certain circumstances, rejected. Albert also calls this the *principle of feasibility*.

Another bridge principle suggested by Albert is called the 'congruence postulate': Norms or values, which, to make sense assume the existence of scientifically unknowable factors or entities, should be rejected. Our normative constructs must, therefore, if we wish to comply with the congruence postulate, be consistent with the scientific world view.

Albert did not complete his formulation of bridge principles, but rather left the development of further principles for scientific research to be developed by others. Taken all together, he draws a positive balance on Ethics:

> It is therefore possible to overcome the positivist resignation in questions of moral philosophy, without falling into the existentialist cult of engagement, which replaces rational discussion of such problems with irrational decisions. The critical philosophy, which provides us with this possibility, also has in itself moral content. Whoever assumes this approach for himself has not decided for an

> abstract principle void of existential meaning, but rather for a way of life. An immediate ethical consequence of critical philosophy is that unshakeable faith, which is rewarded in some religions, and is inaccessible to rational argument, becomes a vice rather than a virtue.
>
> Albert 1968/1991: 94 f.

Criticism of Religion

Since the 1970s, Albert has repeatedly occupied himself with the subject of Theology, subjecting the arguments of prominent theologians like Hans Küng or Josef Ratzinger to critical analysis. In doing so, Albert wanted, among other things, to show that no rational solution exists to the *theodicy problem*: how can suffering in the world be reconciled with the idea of an infinitely good and infinitely powerful God?

Albert sees the world today as a world in religious crisis. People are no longer prepared to accept uncritically the dogmas and privileges of the great institutionalized churches, i.e., the Protestant and Catholic Churches, and they are turning to new religious movements which compete with the traditional churches for members. Albert argues for an ethics of 'practicing charity' in the tradition of Albert Schweitzer, but he rejects the traditional belief in God. He considers life after death and rewards in the hereafter for suffering in this life to be illusions. Instead, he argues for an – admittedly highly fragile – autonomous meaning of life of the individual:

> There cannot be a guarantee that our finite lives on earth have meaning. Such a life can in any case only have meaning, to the extent that we fill it with meaning, by facing tasks, the completion of which we find important, by devoting ourselves to activities which are intrinsically satisfying or which help us to fulfill our chosen tasks. The fact that all the happiness on earth is temporary, is not in itself a reason to see this happiness as worthless, and the transience of all things, also those, which we cherish most, does not make the value we have given them in any way illusory.
>
> Albert, 1984. Der Sinn des Lebens ohne Gott. In Hoerster, N. (Ed.), Religionskritik. Arbeitsbuch für den Unterricht, Stuttgart, p. 120

Appraisal

As a philosopher of science and social scientist, Albert made substantial contributions to establishing in Germany (again) an empirically oriented style of thinking, directed toward clarity of thought and rational verifiability, as has prevailed in the social sciences of Anglo-Saxon countries for many years. It is not an exaggeration to say that this style of thinking also clearly dominates the German-speaking world today, some 60 years after Albert's first scientific publication.

Albert's efforts were also influential in raising awareness of the importance of scientific knowledge based on factual evidence in subjects such as economics and law. In any case, it appears that a rethinking has started in the field of Economics in the wake of the world financial crisis, which all the mathematical models were unable to predict, let alone contain. There are also more and more voices in the field of Law, calling for a convergence with Albert and American legal realism. The notion that laws are not an expression of some higher reason, but are simply the means at the disposal of the legislature to bring about intended social changes, should in the meantime be commonplace.

Hans Albert has succeeded in reestablishing in the German-speaking world the tradition of critical social thought, which had been banished here in the 1930s and early 1940s. If one wanted to describe him and his work in a single phrase, *Defender of the Enlightenment* would probably be most apposite.

Alcohol Interventions: Disease Models vs. Harm Reduction

Thomas Hall, University of Central Florida, Orlando, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The disease model of alcoholism is based on the assumption that alcoholism is an incurable, progressive disease. Abstinence from any alcohol use is prescribed within the disease model. In recent years, harm reduction has emerged as an alternative to the disease model. Harm reduction is based on a public health approach to alcohol abuse. The public health model recognizes the benefit of progressive steps toward decreasing alcohol use and associated physical and emotional harm. Evaluation research and survey data indicate that a public health approach is a viable alternative to the disease model.

Introduction

Typically a lag exists between dissemination of scientific innovation and clinical practice. This is especially true of alcohol-dependency treatment. Applied social and behavioral studies provide both researchers and clinicians opportunities to meet the challenges of responding to contemporary norms, attitudes, and beliefs about alcohol dependency. Evaluation of intervention strategies allows for the development of best practices.

The examination of alcohol abuse treatment efforts starts with a brief review of three treatment modalities and is followed by a description of three types of peer-led support groups. The treatment modalities were the basis of the Project MATCH and COMBINE study interventions. Peer support groups are discussed because of the confusion that exists in the general population regarding the difference between treatment and support. Each peer-led support strategy reviewed is based on one of the treatment modalities examined.

The Project MATCH and COMBINE studies were benchmark studies funded by the National Institute of Alcohol Abuse and Alcoholism (NIAAA) (Willenbring, 2008; Bühringer and Pfeiffer-Gerschel, 2008; Anton et al., 2003). The design of each study allowed researchers to determine the efficacy of a range of treatment alternatives and a philosophy of care. Both studies led to innovation in the delivery of substance abuse treatment. The evaluation literature of non-disease-based treatment modalities was scant prior to both Project MATCH and COMBINE (Willenbring, 2010).

In addition to Project MATCH and COMBINE, the results and implications of the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC) impacted the delivery of alcohol-dependency treatment. The NESARC was a longitudinal survey designed to estimate the prevalence of alcohol use disorders and assess changes over time. The first wave of interviews was conducted in 2001–2002 and the second wave in 2004–2005.

A brief history of research and evaluation of alcohol dependence follows. In addition, the disease model of alcoholism is compared to the public health model. Harm reduction is an important component of the public health model, but it is not universally accepted. Critics contend that harm reduction does more harm than good. Typical treatment modalities are also reviewed, along with aftercare or peer support groups. Lastly, the impact of Project MATCH, COMBINE, and NESARC on the treatment of alcohol use disorder is reviewed.

The Center for Alcohol Studies

After the repeal of prohibition, scientists were eager to study the medical characteristics of alcohol use. The Center for Alcohol Studies at Yale University was the first academic research group created to study alcoholism (Freed, 2011). The center evolved from an interest group in the Applied Physiology department at Yale University in 1935. The aims of the center were the investigation of alcoholism and the development of medical treatments to treat alcohol use disorder. During the 1940s and 1950s, the center was the primary home for alcohol use research and treatment in the United States. In 1961, the center relocated to Rutgers University where it remains to this day.

E. Morton Jellinek, a biostatistician and founding member of the center, was the first to systematically study behavioral traits of alcoholism (Candon, Ward and Pandina, 2014). He surveyed a convenience sample of Alcoholics Anonymous (AA) members in New England. Based on his findings, he hypothesized that alcoholism was a result of 'disease process.' Jellinek proposed that the difference between alcohol use and the disease of alcoholism was a loss of control over drinking. Despite methodological flaws, his work framed alcoholism research and treatment for almost two decades.

The Disease Model of Alcoholism

The disease model was officially recognized by the American Medical Association in 1958. The American College of Physicians recognized alcoholism as a disease in 1969. Early on, the disease model was imprecise in identifying those who suffered from this relatively new diagnosis. Alcoholism could be diagnosed based on concerns about problematic drinking reported by family members or close associates or by clinical observations.

Defining alcohol as a disease implies there is a cure or at least some palliative to be found through medical treatment. For most, treatment for alcoholism required abstinence from alcohol use and participation in self-help groups, such as AA.

The concept of alcoholism as a disease replaced the stigma of moral censure and criminal punishment. Stanton Peele, a critic of the disease model, has noted, "Perhaps the most dire consequence of the disease model of addiction is that it has encouraged the abdication of individual responsibility for outrageous conduct" (Peele, 1989; p. 21). He concluded, "creating a world of addictive diseases may mean creating a world in which anything is excusable" (Peele, 1989; p. 16).

Legal, religious, and behavioral or medical 'experts' defined alcoholism as a physical condition that must be socially constrained and medically treated. Addictions therapists were granted 'expert' status to treat alcoholism. Historically, behavioral health treatment in America was divided into two camps, mental health providers and addiction providers. Mental health providers typically earned terminal degrees, whereas addiction providers often did not. Substance abuse treatment was the purview of recovering 'addicts,' while behavioral health providers were located on the periphery. This schism between researchers and addiction providers exists today. Addiction providers are typically cautious about adopting new approaches to treatment (Walters and Rotgers, 2012).

Harm Reduction and the Public Health Model

In the late twentieth century, the public health model of alcohol intervention changed the narrative from curing disease to promoting health (Russell et al., 2011). Prevention and treatment of alcohol abuse included non-recovering addiction providers. Harm reduction strategies now aimed to manage symptoms and decrease risk versus curing a disease. Harm reduction influenced the shift from the disease model to the public health model of prevention and treatment. There was a great deal of angst among treatment-as-usual addictions providers such that non-recovering researchers, psychiatrists and physicians, sociologists, and psychologists did not understand the implications of harm reduction. Perhaps lost in this conversation was an acknowledgment that the founders of the Center for Alcohol Studies were also non-recovering scientists. Their development of the disease model was, at the time, an effort to get people to look on alcoholism as a disease as opposed to a moral failing or character flaw.

As early as the 1970s, Alan Marlatt, Linda, and Mark Sobell challenged assumptions that alcoholism was an incurable disease (Sobell and Sobell, 1978; Marlatt and Dillworth, 2005). They were key figures in speaking out for change. They advocated for the inclusion of moderate drinking as an alternative to the prevailing abstinence-only injunction. Harm reduction was based on a continuum of alcohol consumption that ranged from heavy drinking to abstinence. Alcoholic patients were taught how to reduce the quantity and frequency of their alcohol use as well as associated negative consequences. Marlatt encouraged individuals to choose the goal that best fits their needs.

In the 1990s concerns related to college drinking led to several interventions. Marlatt developed health promotion programs for students based on teaching how to drink responsibly (Baer et al., 1989). His interventions taught college students harm reduction tactics and controlled drinking strategies. His campus harm reduction programs remain germane to college health in the twenty-first century (Dimeff et al., 1999; Whiteside et al., 2010).

Managing consequences associated with alcohol abuse was a significant conceptual shift. Harm reduction encourages goals of safer drinking, reduced drinking, moderate drinking, or abstinence. Critics of harm reduction point out that tolerating risky or illegal conduct sends the message that risk-laden behaviors are acceptable. They also characterize harm reduction as ineffective. They assume it does not reduce harm and over time may increase negative consequences.

Project MATCH Intervention Strategies

Project MATCH was the first multisite federally funded longitudinal study of alcoholism. The study was initiated in 1989 and continued through 1997. The cost of the study was over 27 million US dollars. Project MATCH evaluated the effectiveness of twelve-step facilitation (TSF), cognitive behavioral theory (CBT), and motivational enhancement theory (MET). The study was designed to evaluate the relevance of matching patients with specific treatment modalities. Study investigators tested the assumption that patient outcomes were related to the fit between treatment modalities and individual patient characteristics.

Cognitive Behavioral Therapy

CBT is based on both Pavlov's theory of classical conditioning and B.F. Skinner's theory of behavior modification (Tatarsky, 2002). Behaviorism could not account for all types of behavior; hence CBT was developed to integrate abstract thoughts and feelings with concrete behaviors. CBT has been typically described as problem focused and action oriented. Individual choice is an important construct. Clients are accountable for their cognitive approach to 'problems' and their choice of behaviors. Action is located in the here and now (Tatarsky, 2002).

CBT does not ignore past trauma, shame, or guilt; however, action and accountability cannot occur in the past or future. Action is possible only in the present. Within the cognitive behavioral paradigm, all behavior is conceived of as changeable if clients are motivated to change. Clinicians structure session content to increase interpersonal competence and decrease interpersonal vulnerabilities. Substance abuse intervention utilizes cost/benefit analyses, decisional balancing, and relapse prevention planning. These techniques require the client to engage actively in the present through the use of behavior logs. For example, drink-monitoring cards record the elapsed time and number of standard drinks an individual consumes in a given day and the social context of their drinking behavior. Clinicians process their daily drinking logs with patients to assess any manifestation of cognitive dissonance.

Motivational Enhancement Theory

MET was designed to encourage a feeling of optimism among stigmatized individuals (Scholl and Schmitt, 2009; O'Leary Tevyaw and Monti, 2004; Miller and Rose, 2009). MET

focuses on the level of insight or awareness individuals exhibit regarding the risk associated with their alcohol use. Stein et al. (2009) found that integrating MET techniques in the earliest phases of treatment had positive effects on patient engagement over the course of treatment. Motivational interviewing strategies include the use of open-ended questions, reflective listening, affirmations, and summarizing. MET evaluates patient 'readiness for change' on a continuum that begins with little insight (pre-contemplation) and moves progressively toward self-determination (action and maintenance).

Twelve Step Facilitation Therapy

TSF therapy is based on the first five traditions of AA. TSF assumes that alcoholism is a progressive illness that affects the body, mind, and spirit for which the only effective remedy is abstinence from the use of alcohol (Donovan et al., 2013). TSF posits that without treatment, patients do not accept the reality of their loss of control over drinking. Alcoholism impairs coping mechanisms and interpersonal relationships and ultimately leads to alienation from self and others.

TSF encourages patients to accept that they are victims of a progressive, incurable disease and to surrender their will to a 'higher power.' Kelly et al. (2012) found that the main effect of TSF was the changing of patients' social network and relationships with family members and associates. In addition to alcohol abuse treatment provided by professional counselors, participation in peer-led 12-step support groups improved treatment outcomes. Dawson et al. (2006b) found that 12-step participation posttreatment doubled the chance of abstinence as compared with attendance in formal treatment and no 12-step participation. Dawson asserted that participation in 12-step programs was noteworthy for achieving and maintaining abstinence. Streifel and Servanty-Seib (2006) surmised that participation in AA provided needed social support to manage anger, loss, and grief associated with sobriety.

Aftercare: Selected Peer-Facilitated Support Groups

Support groups are an important adjunct to formal treatment (Kelly et al., 2006). Support groups provide opportunities for individuals in recovery to develop coping skills to manage their sobriety. An important factor in the success of support groups is a belief that recovery from alcoholism is possible. Listening to the successes and setbacks of others who are alcohol dependent can inspire hope for change. Recovery becomes a real experience, separate from the prescribed therapeutic factors of professionally led treatment programs. Twelve-step support groups are the most widely recognized peer-facilitated support groups.

Other peer-facilitated groups have been successful in supporting abstinence or reductions in substance use. SMART Recovery is a non-faith-based alternative to AA (Horvath, 2000). Both SMART Recovery and AA support groups are based on abstinence from alcohol or any other illicit substance use. SMART Recovery is grounded in CBT and offers a 'tool kit' for members to assist with managing cognitive distortions or irrational beliefs that lead to maladaptive coping mechanisms.

The Harm Reduction, Alcohol Abstinence and Management Support (HAMS) is also based on CBT (Anderson, 2010). However, HAMS is not an abstinence-based support group. HAMS incorporates stages of change theory and harm reduction, and meets individuals 'where they are' as opposed to where others believe they need to be. Harm reduction-inspired support groups remain controversial as critics contend they lead to relapse and do more harm than good.

Alcoholics Anonymous

The 12-step support group AA is the largest of all the 12-step programs. Narcotics Anonymous is the second largest and accommodates members who are recovering from addiction to alcohol and other drugs. However, there are over 30 different 12-step support groups covering a broad range of addictions. Each group is unique in its behavioral manifestation of addiction, yet all have the same recovery goals: physical, mental, emotional, and spiritual well-being.

The 12-step programs are grounded in the disease model. The physical dimension has been described as an allergen. Those who are afflicted with the disease of alcoholism cannot drink moderately. A core belief has been the 'powerlessness' of an individual over substance abuse. This was a key premise in Jellinek's disease concept. These groups advocate that the admission of powerlessness within a nonjudgmental social support system creates a context where letting go of shame and guilt is possible. Spiritual components of the program are included to instill hope for change. The process of working through universal 'steps' is intended to replace self-centered beliefs and actions with an awareness of the feelings and needs of others.

SMART Recovery

SMART Recovery was developed as a peer-facilitated support group based on cognitive behavioral strategies. MET and recognition of individual readiness to change underlie the SMART Recovery goals. Self-sufficiency and self-confidence are fundamental features of SMART meetings. SMART Recovery promotes self-directed change.

SMART Recovery advocates for the use of psychological treatments and physician-prescribed medication that manage urges to drink or mediate the physical effects of drinking. SMART Recovery adapts its educational material to incorporate new-scientific innovations. SMART Recovery supports (1) individual progression toward motivation to remain sober; (2) strategies to cope with urges to drink; (3) dealing with attitudes, beliefs, and behaviors; and (4) mindfulness. Similar to AA, SMART Recovery promotes abstinence as the best outcome for managing alcoholism.

Harm Reduction, Abstinence, and Moderation Support

Similar to SMART Recovery, HAMS also provides peer-group support that does not promote faith-based norms. However, unlike SMART Recovery, HAMS is not abstinence based. HAMS

is informed by harm reduction within this paradigm; harm reduction is defined as a nonjudgmental approach that provides individuals with support to make desired changes in their behavior. HAMS attracts individuals who are interested in reducing alcohol-related harm or reducing alcohol use.

HAMS does not prescribe 'acceptable' alcohol use. HAMS accepts that for some, alcohol intoxication is not stigmatized, and the support groups teach individuals how to reduce harms. One of the concerns associated with AA is the loss of individual autonomy connected to powerlessness. A tolerance for and acceptance of individual choice distinguishes HAMS from other peer-facilitated support groups. The focus of HAMS is alcohol harm reduction; however, individuals who use alcohol and other drugs are welcomed and supported whether they choose safer use, reductions in use, or quitting altogether.

Implications of Project MATCH and COMBINE Research

Epidemiologic studies, such as Project MATCH and COMBINE, highlight the need for a change of focus in addiction treatment (Roizen and Fillmore, 2001). Project MATCH and COMBINE results demonstrated that effective treatment was multidimensional. No single strategy accounted for decreased substance use and associated harm. Project MATCH validated the efficacy of three types of behavioral interventions. It also challenged existing beliefs about effective treatment. The belief that some individuals would benefit from one treatment while others would benefit from another was discredited.

The Project MATCH study found that the patient–treatment matching did not significantly influence study outcomes. Treatment techniques did not predict treatment effectiveness (Moos et al., 1999; Babor, 2008). However, Project MATCH results also raised questions about the efficacy of any substance use treatment. The study results left some evaluators with two assumptions. The first assumption indicated that multiple treatment interventions work; one intervention was not more effective than the other. The second assumption indicated that none of the treatments made a difference. While some found the study results reassuring and interpreted these to be proof of the benefits of existing strategies, others suggested that none of the treatment modalities were notably effective.

Critics claimed that treatment success had less to do with treatment modality and more to do with subject perseverance and motivation. If methodical differences between interventions did not influence treatment success, then what did? Cutler and Fishbain (2005) suggested that the study results were a result of motivation. Study subjects who choose to seek treatment were more likely to reduce their drinking, and those who reduce their drinking are more likely to continue in treatment. Cutler and Fishbain noted the similarities between Project MATCH study results and those seen in studies of depression. The act of enrolling in a study sometimes leads to improvement in symptoms prior to the initiation of treatment (Cutler and Fishbain, 2005).

Stanton Peele (1998) challenged the relevance of Project MATCH study conclusions. Similar to Cutler and Fishbain's comments, Peele suggests that the study design was flawed because of the lack of a nontreatment control group. Peele also questioned why drinking frequency and quantity reductions were considered positive treatment outcomes for all treatment modalities. The TSF treatment manual stated intervention goals were consistent with AA abstinence goals; therefore, he asks if any effect other than abstinence should be coded as treatment failure for the TSF facilitation group. Alan Marlatt observed that the study left ample room for anyone to use the results to bolster their ideological point of view (Bower, 1997).

The COMBINE Study

The results of the COMBINE study challenged traditional definitions of effective treatment for alcohol dependence (Willenbring, 2010). The study was the first to compare the effects of pharmacotherapies and behavioral or psychosocial intervention on treating alcohol abuse and dependency. The study is the largest alcohol-use-related pharmacotherapy research project to date. The study evaluated the efficacy of medical management, psychopharmacology, and a Combined Behavioral Intervention (CBI). The COMBINE study randomly assigned alcohol-dependent patients to one of nine different treatment conditions. Eight of the groups received a combination of medical management, pharmacotherapy, and CBI. One group received CBI only.

The efficacy of two oral medications (naltrexone and acamprosate) was tested. The study indicated medical management using naltrexone was beneficial for the treatment of alcohol abuse and dependence; however, acamprosate was not (Anton et al., 2006). This result was surprising given the results of previous studies that reported acamprosate was effective (Willenbring, 2010). The study found that naltrexone reduced relapse rates after treatment. Naltrexone is designed to act as an opioid receptor antagonist and is used primarily in the management of alcohol dependence and opioid dependence. However, the primary use of naltrexone has been for the treatment of alcohol dependence. In addition to decreasing relapse among alcohol-dependent patients, heavy drinking patients who chose to moderate their drinking also benefitted from naltrexone.

The COMBINE study indicated that cognitive behavioral interventions used in tandem with naltrexone yielded the most favorable results. However, placebo pills and meeting with a health-care professional also had a positive effect (Anton et al., 2006). The efficacy of naltrexone led to increased numbers of alcohol-dependent patients being treated in ambulatory medical settings, thus increasing opportunities for patients to be served outside of substance abuse treatment facilities. The COMBINE study provided a framework for medical management in health-care settings.

Results of the COMBINE study led a new generation of physicians to consider pharmacology as well as behavioral health strategies for the treatment of substance abuse. A better understanding of the neurobiological effects of alcohol and other drugs has led to the development of new pharmacotherapies. The COMBINE study found that the best treatment outcome included medical management, medication, and behavioral counseling. The assertion that traditional behavioral counseling alone is the least effective treatment has been controversial. Abstinence-only treatment programs that do not endorse pharmacotherapy dispute this finding.

National Epidemiologic Survey on Alcohol and Related Conditions

The NESARC is the most comprehensive alcohol-use survey to date. Data were collected regarding individual and family history of addiction and treatment, as well as comorbid psychological and psychiatric disorders. The results of this survey indicate most people who meet the criteria for alcohol dependence never seek professional help (Willenbring, 2010). These survey results led researchers to examine under what circumstances people recover from alcohol dependence without professional assistance. Spontaneous remission or natural recovery is not a new concept; however, prior to the NESARC estimates of natural recovery, prevalence rates were unknown. Natural recovery has been a topic in substance abuse treatment since the 1980s. Prior to the NESARC, natural recovery was often dismissed as an anomaly or spurious conclusion.

Dawson et al., (2006a) report findings from the NESARC to suggest that one in four participants who met the criteria for problem drinking received professional help for alcohol problems. Klingemann et al. (2010) found natural recovery to be more common among individuals who rejected treatment as usual. The characteristics of subjects who report 'spontaneous' or natural recovery are germane to substance-dependence research.

Characteristics of individuals who reported natural recovery include satisfaction with work, financial security, committed relationships, and less social pressure to quit drinking (Bischof et al., 2001; Dawson et al., 2006b). Russell et al. (2001) found that when drinking interfered with activities of daily living, those who naturally recovered reported less self-examination of their alcohol-use-related problems. They reported fewer disclosures with associates and little pressure to stop alcohol consumption from close associates, as compared to those who reported they were in treatment or had completed treatment. Bischof et al. (2007) found that for these individuals, social support better accounted for their sobriety. Supportive relationships with peers and family, as well as participation in self-help groups, were characteristic of natural recovery (Dawson, et al., 2006a). Granfield and Cloud (1996) found that middle-class subjects were more likely to recover without the help of professional intervention. Increased anxiety and concern about loss of income and class status were also important characteristics associated with natural recovery.

Conclusion

The foundation of scientific inquiry about alcoholism began in the middle of the twentieth century. During this time the Center for Alcohol Studies at Yale University was created. The realization that alcoholism cut across almost every field of human knowledge led the center to assemble a group of professionals that included a physician, a psychiatrist, a statistician, a psychologist, a sociologist, a lawyer, and an economist (Page, 1997). The aim of this group was to understand the mechanisms of addiction and develop effective treatment modalities.

Initial treatment models were based on Jellinek's research on a group of men who attended AA meetings in New England. Jellinek attempted to identify and classify the characteristics of alcoholics. His study was the most comprehensive study of alcoholism at the time. He sought to use the best-available science to improve the lives of those suffering from alcoholism.

In the twenty-first century, scientific inquiry related to genomics, pharmacology, and neuroscience continues to challenge our understanding of alcohol dependency. Because of science, there exists a better understanding of the interplay between genetic, social, psychological, and environmental factors on substance dependence. Understanding the interplay between social and environmental factors better explains how individuals may recover from substance dependence with or without any formal intervention.

Project MATCH and COMBINE contributed to the adoption of new strategies for treating alcohol dependence. The use of pharmacotherapy as an adjunct therapy for alcohol dependence is promising and increasing. The COMBINE study demonstrated the efficacy of psychopharmacological treatments. A greater understanding of the benefit of medical management and psychotherapy resulted from these research studies. The advantage of prescribing naltrexone for patients who have previously failed to respond to psychotherapy alone is encouraging. The success of various treatment modalities and inclusion of medical management indicate that previous assumptions about alcohol treatment are open for debate. Since the 1940s the AA model has dominated the narrative regarding alcohol-dependence treatment. The disease model is almost 75 years old and in many treatment programs the model continues to persist.

Evaluation and dissemination of alcohol use education, intervention, and public policy lead to best practices. Innovation in medical treatment has created opportunities for research and evaluation with regard to evidence-informed care of alcohol-dependence patients. The public health paradigm shifted the emphasis to include education, clinical intervention, and policy development. However, despite the dissemination of research on effective treatment strategies, the majority of community treatment programs in the United States continue to utilize psycho-education interventions and referral to AA as their primary treatment modality (Willenbring, 2010).

Abstract

Alcohol consumption has been shown to be causally related to numerous medical conditions and is a significant cause for psychiatric and somatic morbidity and premature death worldwide. While the repeatedly reported moderate mortality reduction in individuals with low alcohol consumption with a lower risk coronary heart disease and ischemic stroke compared to abstainers is controversial, increased alcohol consumption is related to increased risk for liver disorder and many other medical conditions, as well as injuries or accidents, mostly in a rather dose–response relation. The central nervous system is especially vulnerable to alcohol's effects. Brain damage, epileptic seizures, wernicke-korsakoff syndrome, and alcohol psychoses are frequent in individuals with heavy alcohol intake. Numerous other severe disorders are associated with increased alcohol intake. A brief overview about pharmacological and neurobiological actions of alcohol and its effect in brain and body are given.

Alcohol affects the function of nearly all organs in the body and has numerous effects on metabolism, cell function, and physiologic processes. Acute effects of alcohol (e.g., alcohol intoxication) must be differentiated from chronic effects or the results of harmful use or even dependence. Alcohol significantly affects brain function with numerous clinical consequences both on the neuropsychiatric and behavioral level such as impaired memory, cognitive decline, blackouts, seizures, or others. Chronic alcohol consumption can lead to severe organ damage most frequently of the liver but numerous other parts of the body may also be affected. A brief update on the metabolism and pharmacology of alcohol and its general effects in the body is given before more distinct effects on cognitive function, mental processes, body function, and health are outlined. Finally, distinct neuropsychiatric disorders and somatic complications of alcohol dependence are described.

Alcohol (ethanol, C_2H_5OH) is a relative simple molecule, which interacts with numerous transmitters and receptors in the body and brain and also changes structure and function of cells and cell membranes, among others. Virtually, every organ is affected by acute or chronic alcohol intake. It is difficult to define definite cutoffs for risky alcohol consumption. The British Medical Association in 1995 considered 20 g of alcohol for women and 30 g for men as the upper limit for nonrisky alcohol use. More recently, the recommended upper limits for alcohol consumption are about 24 g for men and 12 g for women. Acute effects of alcohol, for example, on blood pressure, circulation, or brain function must be differentiated from more chronic ones like liver dysfunction or withdrawal. Since alcohol's effects in the body are so complex, only a brief overview on its basic mechanisms are given before addressing clinically relevant disorders associated with alcohol consumption.

Alcohol – Metabolism and Pharmacology

Alcohol is quite rapidly absorbed after oral ingestion in the stomach. About 95% of alcohol is oxidized in the liver by the enzyme alcohol dehydrogenase (ADH) to acetaldehyde, which in return is rapidly metabolized by the enzyme acetaldehyde dehydrogenase (ALDH) to acetic acid, which is also rapidly converted to carbon dioxide and water. Only 5% of alcohol is excreted unchanged in the urine, sweat, and breath. There is a genetic polymorphism for both enzymes with different isoenzymes. While most (>90%) of the Caucasian population have 'regular' ALDH isoenzymes, other – especially Asian populations have so-called ALDH-deficient isoenzymes (30–50%) with significant acetaldehyde levels in the blood after alcohol intake. In these individuals, alcohol consumption rapidly results in aversive reactions, so-called 'flush reaction.' Alcohol is usually metabolized at a rate of 0.1–0.15 (or 0.2) mg l^{-1} per hour.

Genetics

There is substantial evidence from a number of family, twin, and adoption studies for a genetic transmission of alcoholism. The risk for alcoholism is significantly increased in first-degree relatives of alcoholics. Some adoption studies have shown an up to four times increased risk for alcoholism for sons of alcoholics even if they were raised apart from their biological parents. Although the heritability of alcoholism is a topic of numerous biological and genetic studies on the genetic and molecular/biological level, no vulnerability marker or gene for alcoholism is definitely identified yet. It seems most likely that alcoholism is not transmitted by a single but a number of genes. Alcoholism appears to be a polygenic disorder. Also no definite genetic marker for alcoholism is found yet. Numerous genome-wide scans to identify genes mediating the risk for alcoholism have been initiated in recent years, with conflicting results. The most robust findings come from chromosomes encoding for alcohol-metabolizing enzymes, especially genetic variations of ADH and ALDH. Other candidate genes are those mediating the pharmacogenetic response to alcohol, such as mu opioid or gamma-aminobutyric acid (GABA) receptor genes.

There are marked differences not only in alcohol metabolism but also in tolerance. Experimental and follow-up studies have shown that high-risk individuals (children of alcoholic parents) usually tolerate alcohol much better than other individuals. This in part explains the increased risk for alcoholism.

General Effects of Alcohol

Brain (Central Nervous System Effects)

Different from other psychoactive substances like opioids there is no special alcohol receptor in the brain. A number of neurotransmitters are involved in mediating alcohol's effects including GABA, glutamate, dopamine, opioids, serotonin, and noradrenalin, among others. Alcohol is a psychotropic agent that depresses the central nervous system (CNS) basically via enhancement of GABAergic neurotransmission. GABA is the most important inhibitory neurotransmitter in the brain. Acute alcohol intoxication results in enhancement of inhibitory neurotransmitters (GABA) and antagonization of excitatory neurotransmitters (glutamate, dopamine, etc.) while the neurotransmitter function in alcohol withdrawal is the opposite (increased activity and release of excitatory, inhibition of inhibitory neurotransmitters). Thus alcohol withdrawal results in an increased excitatory state in the brain, possibly leading to seizures or delirium.

The rewarding, psychotropic effects of alcohol are in part mediated by dopamine, opioids, GABA, glutamate, and serotonin. There seems to be a special addiction memory in the brain, which in part involves brain structures, which are of relevance for physiologic reward processes and controlling of food and fluid intake and sexuality. One of the key structures in the brain mediating these reward effects is the dopaminergic mesolimbic system including the nucleus accumbens. Activation of this system leads to positive reinforcement. Alcohol but also other psychotropic drugs are believed to act predominantly by interactions with neurons in these brain areas.

Alcohol also directly acts on neurons in the CNS. It not only alters the properties of lipids in the membrane of neurons but also has direct neurotoxic effects at least in higher concentrations. Chronic alcohol intake may result in cell damage and destruction of neurons in the brain but also in other regions of the body. Other alcohol-related factors such as vitamin deficiencies or malnutrition in general may contribute to the neurotoxic effects. Although alcohol-related cell loss can be found in all brain areas, the forebrain and the cerebellum are mostly affected in chronic alcoholics. To some extent cell losses in the CNS can be visualized *in vivo* by modern neuroradiological techniques such as cranial computer tomography scans or NMR.

Effects on Cognitive Function and Mental Processes

Modest alcohol intake may cause a number of emotional changes such as sadness, anxiety, or irritability that predominantly occur at peak or with decreasing blood alcohol concentration (BAC). Alcohol in higher doses can cause following psychiatric syndromes: (intense) sadness and anxiety, auditory hallucinations, and/or paranoia without clouding of sensorium. These syndromes can be classified as organic brain syndromes or alcohol psychosis. The former is characterized by mental confusion and clouding of sensorium, which can be found during alcohol intoxication usually at a BAC over 1.5 mg l^{-1}, withdrawal, or as a consequence of alcohol-related disorders.

Behavioral Changes

They depend on age, weight, sex, prior experience with alcohol (e.g., the individual's drinking history), and age. Symptoms of alcohol intoxication are described below.

Tolerance

There are marked differences in alcohol tolerance between individuals, partially due to genetic variances in alcohol metabolism. For a number of not fully understood reasons tolerance in men is usually better than in women. Women have less water in their body so alcohol is less diluted and has greater effects in the tissue. The individual alcohol history (heavy or regular vs sporadic consumption), liver function, organic brain syndromes, or other disorders have marked impact on alcohol tolerance, which is usually increased in heavy drinkers and alcohol dependents, except for those late-stage drinkers with severe physical (liver!) or mental impairment. Some studies in high-risk individuals (offspring of alcoholic families) have shown that alcohol tolerance is usually better in individuals with positive family history for alcoholism and also to some extent predictive for later alcoholism.

Physical Dependence

Alcohol Dependence

According to modern psychiatric classification systems such as ICD-10 and DSM-IV, alcohol dependence is defined as a cluster of physical, psychological symptoms, and social consequences of alcohol consumption (Schuckit, 2005). The categorical distinction between abuse (harmful use) and dependence has been given up by the very recent DSM-5 toward a dimensional concept. Alcohol use disorders are defined by a problematic pattern of alcohol use leading to clinically significant impairment in different domains. In DSM-5, 11 symptoms are given. Presence of 2–3 symptoms indicates a mild, 4–5 a moderate, 6 or more severe disorder.

In contrast, patients who meet ICD-10 diagnosis of alcohol dependence must display three of the following six symptoms:

1. a strong desire or compulsion to drink;
2. tolerance;
3. withdrawal;
4. loss of control;
5. progressive neglect of alternative activities; and
6. persistent drinking despite evidence of harm.

Physical Withdrawal

Many but not all alcoholics develop physical dependence and experience physical and psychological withdrawal symptoms after cessation of alcohol consumption. A number of physiological mechanisms are involved in the development of the

syndrome. Basically the development of withdrawal symptoms can be explained by a number of adaptive mechanisms resulting from long-term alcohol intake. While alcohol enhances the neurotransmission of inhibitory neurotransmitters (GABA) and blocks excitatory neurotransmitters (glutamate, etc.) during alcohol withdrawal, there is an increased excitability in the CNS and an autonomic nervous system dysfunction with an excess release and turnover of excitatory neurotransmitters.

Symptomatology of alcohol withdrawal covers a wide range of symptoms, which develop few hours after the last drink with a peak on day two or three, which usually subsides within 4 or 5 days. While alcohol withdrawal is usually mild in some cases a severe withdrawal syndrome can develop. Key symptoms are tremor, insomnia, malaise, anxiety, inner restlessness, sweating, increase in heart and respiratory rate, mild elevations in temperature, gastrointestinal symptoms such as anorexia, nausea, and vomiting, and psychological or emotional symptoms such as anxiety or sadness. A broad number of other symptoms may also be prevalent, depending on the patient's physical condition. In more severe cases, seizures (5–10% or more of patients) or hallucinations may complicate the clinical course. The most severe variant of alcohol withdrawal is alcohol withdrawal delirium.

Depending on the clinical course and symptomatology, inpatient or outpatient detoxification can be necessary. Pharmacological treatment includes fluid intake, substitution of vitamins and minerals, and sedatives, predominantly benzodiazepines or clomethiazole (in Europe only).

Effects on the Body and Health

Alcohol in light to moderate doses may have a slight beneficial effect in decreasing the risk for cardiovascular disease by increasing high-density lipoproteins (HDLs) although this issue is still controversial. In any case, this effect is far outweighed by the health risks in individuals with heavy alcohol consumption. Mean effects of alcohol in the body are as follows:

1. Cardiovascular and cerebrovascular system: hypertension, heart inflammation, or more often myocardiopathy, arrythymia.
2. Brain: intracerebral hemorrhage. Other data indicate that mild to moderate alcohol consumption ($<50\ \mathrm{g\ day^{-1}}$) may have some protective effect on the cerebrovascular and cardiovascular system, possibly by effects on blood lipids (inhibition of elevated low-density lipoprotein (LDL) cholesterol, increase of HDLs) and some antiatherogenic and antithrombotic effects.
3. Neuromuscular system: polyneuropathy, myopathy, autonomic disorders.
4. Digestive system: increased rate of gastritis and ulcer disease, pancreatitis (possibly followed by diabetes), abnormal functioning of the esophagus including esophagitis.
5. Liver: fatty liver, acute alcoholic hepatitis, chronic active hepatitis, and, finally, cirrhosis. From a chronic alcohol intake of 20 g for women and 30–40 g for men the risk for liver damage is already increasing.
6. Blood cells: the production of all types of blood cells is decreased. Red blood cell anemia (macrocytosis), decrease of white-cell production and function, and decreased production of platelets and clotting factors are the result. Function of thymus-derived lymphocytes, which are essential for immune function, is also impaired.
7. Sexual functioning and hormonal changes in men testicular atrophy, hypogonadism, decreased sperm production and motility, decreased testosterone production, and sometimes impotence are typical results of chronic alcoholism. In women, menstrual irregularities are of relevance, as are effects on the fetus.
8. Other endocrine and metabolic effects of alcohol include impaired thyroid and parathyroid function with an increased risk for osteoporosis and bone fractures. The glucose and carbohydrate metabolism is affected in complex ways. A frequent complication of alcohol is also diabetes, mostly due to pancreatitis.
9. Skin: a number of dermatological conditions can be provoked or worsened by alcohol: porphyries, psoriasis vulgaris, rosacea, cancer of the oral mucosa, pellagra, and others.
10. Increased risk for cancer of the mouth and digestive tract (pharynx, larynx, esophagus, stomach, liver), head and neck, lungs, and breast. A number of variables contribute to this phenomenon: alcohol toxicity, comorbid nicotine dependence (smoking), malnutrition, decrease in immune function, among many others.
11. Malnutrition, vitamin deficiency, and electrolyte changes. Typically chronic alcoholism is associated with some form of malnutrition. Typical effects of chronic alcoholism are zinc deficiency, hypokalemia, deficiencies of vitamin B ($B_{1,3,12}$), vitamin C, and folic acid, among many others.

Morbidity and Mortality

The mortality and morbidity of individuals with heavy alcohol consumption, harmful use, or alcohol dependence are significantly increased compared to the general population. Reasons are multifactorial such as there are numerous somatic and neurologic disorders related to alcohol, also the risk for accidents and suicide is much higher in alcoholics. In addition, the alcoholic's lifestyle (nicotine consumption, low-protein/high caloric food, etc.) also contributes to the increased morbidity and reduced life expectancy in alcoholism. Some studies indicate that 5% of all deaths are related to alcohol consumption.

Alcohol Embryopathy (Fetal Alcohol Syndrome)

A tragic and often underestimated result of drinking during pregnancy is alcohol embryopathy. Key features are intrauterine growth retardation, microcephaly, moderate to severe mental retardation, and relatively typical dysmorphologic facial malformation. Many other symptoms may also be present such as internal and genitourinary malformations, especially congenital heart defects, among many others. The degree of alcohol embryopathy is correlated to the stage of maternal alcohol illness, not to the maternal alcohol consumption.

Psychiatric Complications

A number of distinct neuropsychiatric disorders are caused by chronic alcohol intake including delirium, psychosis, anxiety, and depression and an increased risk for suicide/delinquency. There is a high comorbidity of alcoholism with depression, schizophrenia, antisocial personality, and other personality disorders, anxiety, and addiction to other substances and drugs including tobacco. Alcoholism sometimes develops prior to the psychiatric disorder but in many cases it is secondary, worsening the clinical course and symptomatology.

Driving Ability and Accidents

Alcohol has major effects on driving ability as well as the risk for accidents. These factors contribute significantly to the increased morbidity and mortality in alcoholics. Even at a BAC of 0.15 mg l^{-1} the ability to operate a motor vehicle is significantly impaired. The risk, especially for more severe accidents, rises dramatically with increasing BAC. There are marked differences concerning permitted BAC while operating a motor vehicle in different countries. Some countries do not allow any alcohol intake, while in most states 0.5 or 0.8 mg l^{-1} BAC are the upper limits tolerated. The risk for other accidents (home, workplace, sports) also rises with increasing BAC.

Nervous System

Alcohol Intoxication

Probably, the most frequent alcohol-related disorder is alcohol intoxication. Although there is no strict correlation between blood alcohol level and behavioral or motor impairment the symptomatology depends on BAC, individual alcohol tolerance, and a number of confounding factors such as physical and psychiatric status, intake of other substances, sleep deprivation, among others. Alcohol intoxications can be classified as mild (BAC 0–1 mg l^{-1}), moderate (BAC 1–2 mg l^{-1}), and severe (BAC over 2–2.5 mg l^{-1}). The higher the BAC, the more pronounced are the CNS depressant, sedative effects, and the behavioral dysfunction. Light to moderate alcohol intoxication is usually associated with relaxation and feelings of euphoria as well as impaired coordination. Higher BAC results in severe cognitive, perceptual, and behavioral impairment. This includes blackouts, insomnia, hangover. On the physical level alcohol intoxication is associated with hypertension, cardiac arrhythmia, gastrointestinal symptoms such as vomiting, diarrhea, abdominal pain, nausea, anorexia, gastritis, and hepatitis. Neurological symptoms include ataxia, fainting, and blackouts. Trauma and accidents (traffic safety!) are of special relevance. On the psychological and behavioral level insomnia, anxiety, depression, sexual problems, and inappropriate, aggressive or impulsive behavior may occur. Severe cognitive impairment, clouding of sensorium, disorientation, and amnesia can be found in higher BAC. Mortality is significant in BAC >4 mg l^{-1} due to respiratory paralysis, heart failure, and coma.

Pathological Intoxication (Alcohol Idiosyncratic Reaction)

In some individuals (although extremely rare), mild to moderate alcohol intoxications can be associated with severe aggression and violence or psychotic reactions lasting for a few hours and usually followed by a more or less complete amnesia. The psychiatric and behavioral symptoms are very marked and cannot be explained by the comparatively low BAC level. This syndrome, which is basically of forensic interest, is very controversial among clinicians. Possible predisposing factors are hypoglycemia or other metabolic disorders, organic brain syndromes, or intake of other psychotropic drugs such as stimulants.

Delirium

Delirium usually starts during the first 4–7 days after cessation of alcohol consumption. Key features of delirium are clouding of sensorium, disorientation, severe confusion, fear and agitation, visual and sometimes acoustic hallucinations, delusions of persecution, or others. Delirium is a very serious medical disorder, which is more common than other alcohol psychosis (prevalence rate about 1%) and has a significant mortality if untreated. Symptoms found in alcohol withdrawal can also be seen in alcohol delirium but are usually more severe. The clinical condition is characterized by a severe overactivity of the autonomic nervous system (increased pulse rate and respiratory rate, marked elevation in blood pressure and body temperature). Frequent complications are seizures, cardiac arrhythmia, and many other medical disorders. Patients need substantial medical support and psychopharmacological treatment, usually sedatives such as benzodiazepines.

Alcohol Psychosis

Chronic alcohol consumption can result in different alcohol psychoses. In some cases, a more or less chronic state with suspiciousness or more pronounced paranoid delusions can develop. This disorder is referred to as alcoholic paranoia or alcohol-induced psychotic disorder. The prototype of this psychosis is a delusional jealousy syndrome nearly exclusively found in male alcoholics who believe their spouse to have an extramarital relationship. Sometimes without the slightest evidence the alcoholic is convinced about his spouse's infidelity. Predisposing factors for the development of this syndrome are impotence or other sexual dysfunction, cognitive impairment, and a low self-esteem. The delusions often persist into abstinence. Delusional jealousy is a dangerous disorder with the patient often attacking or even killing his spouse.

The other more prevalent alcohol-induced psychosis is alcohol hallucinosis, which is characterized by vivid predominantly acoustic, sometimes visual hallucinations, delusions of reference or persecution, and fear. Other psychotic symptoms may also be prevalent. Different from alcohol withdrawal delirium the sensorium is usually clear and there is no amnesic syndrome for the psychosis. The psychopathology of alcohol hallucinosis closely resembles paranoid schizophrenia but there is no evidence for a common genetic basis. Alcohol hallucinosis, like alcohol paranoia, can develop during heavy

drinking or more frequently within a few days or weeks of the cessation of drinking. In abstinent patients, the prognosis of alcohol hallucinosis is usually good, but in 10–20% a chronic, schizophrenia-like psychosis can develop. Psychopharmacological treatment in alcohol psychosis (neuroleptics, sedatives) is recommended.

Organic Brain Syndrome, Encephalopathy, and Dementia

While some form of cognitive impairment can be found in up to 75% of chronic alcoholic patients approximately 9% of them have clinically manifest organic brain syndrome. Alcohol itself, but also alcohol-related disorders such as malnutrition including vitamin deficiencies as well as indirect consequences of alcoholism, such as head trauma, hypoglycemia, or other metabolic disturbances can cause cognitive dysfunction, mental confusion, and clouding of sensorium. Serious confusion can be seen during alcohol intoxication and withdrawal, as a result of vitamin deficiency (e.g., thiamin), head trauma, extra- or intracranial hematoma, stroke, hypoglycemia, or simply as a result of long-term alcohol intake, or a combination of these factors.

Wernicke encephalopathy, a dramatic, very acute neurologic syndrome with high mortality, is characterized by a classical symptom trias: ataxia, ophthalmoplegia, and mental disorder (clouding of consciousness). Thiamin deficiency is essential for the development of the syndrome. Patients are disoriented or confused, somnolent or even in coma, show oculomotor abnormalities and gait ataxia. There are distinct symmetric punctuate hemorrhagic lesions in certain brain areas. Rapid thiamin substitution is essential for therapy.

Wernicke encephalopathy in many cases is followed by Korsakoff syndrome (alcohol-related amnesic syndrome), which may also develop without prior Wernicke symptomatology. Key features are anterograde and retrograde amnesia, memory loss, and other cognitive impairment. Apathy, passivity, and confabulations are common symptoms. Prognosis is poor.

Other patients show symptoms of a more gradual cognitive decline and other dementia symptoms without distinct neurological symptoms. Alcohol dementia is a difficult diagnosis. A broad number of other dementia forms including Alzheimer's disease have to be excluded before diagnosis can be made. Chronic hepatic encephalopathy also goes along with cognitive impairment but other neurological symptoms can also be found as follows: frontal release signs, hyperreflexia, pyramidal signs, or others. Organic brain syndromes can also be found as a result of other alcohol-related disorders.

Seizures

Epileptic seizures are the most frequent neurological sequelae with prevalence estimates of 15% or more. The exact pathophysiological basis is unclear. Electrolyte imbalances and neurotransmitter dysfunction (GABA, glutamate) are of special relevance. This disorder is independent from duration of alcoholism and there is no evidence for a genetic risk for seizures in these patients.

Seizures usually occur within the first 24 to a maximum 48 h of abstinence and nearly exclusively are of tonic–clonic (grand mal) type. The clinical and neurological status is usually normal. Other seizure types, especially focal seizures indicate a probable focal brain injury (trauma, hemorrhage, etc). Electroencephalogram and cranial computer tomography may help excluding other reasons than alcohol for seizures but are otherwise usually normal. Prognosis for seizures in abstinent alcoholics is good, otherwise the risk for recurrent seizures is high.

Polyneuropathy

This is a frequent complication of alcoholism (prevalence 9–30%). Beside diabetes, alcohol is the most common cause for polyneuropathy. A number of peripheral nerves with sensory, motoric, or autonomic fibers are affected. The sensoric input and in more severe cases, the motoric system and muscle function are impaired. Typical complaints are symmetric burning or stabbing pain in the feet and mild to more severe weakness of the limbs. Polyneuropathy usually gradually develops and the prognosis in abstinent patients is often positive.

Myopathy

Alcohol has myotoxic effects both on skeletal and cardiac muscles. The more dramatic acute myopathy, which can be accompanied by sometimes extended muscle necrosis, hypokalemia, and secondary renal failure has a prevalence of 0.8–3.3%. Chronic myopathy often with subclinical symptomatology is much more common (23–66%). Myopathy can also be secondary to polyneuropathy. While the acute form goes along with painful muscle swelling, tenderness, and muscle cramps, in the chronic form extended weakness in the muscles is reported. A rare subtype is a myopathy related to hypokalemia.

Autonomic Disorders

Alcohol can also affect autonomic nerves and cause various autonomic dysfunctions (both parasympathicus and sympathicus) such as dysphagia, esophageal dysfunction, abnormal pupillary reflexes, impotence, impaired thermoregulation, among many others. Autonomic disorders are seldom isolated but usually accompanied by other alcohol-related disorders.

Cerebellar Atrophy

Up to 30% of chronic alcoholics show some clinical or neuroradiological symptoms of cerebellar atrophy. Histologically, a degeneration of Purkinje cells in the anterior and superior vermis is seen as well as in the cerebellar cortex. The disorder does not correlate with lifetime consumption of alcohol. Other factors such as vitamin deficiency seem to be of relevance. Cerebellar atrophy develops slowly. Key symptoms are dysarthria, gait and stand ataxia, tremor, and nystagmus. Lower limbs show more impairment than upper limbs. Severe forms of cerebellar atrophy cause astasia and abasia. Symptoms are often at least partially reversible in cases of abstinence and vitamin substitution.

Cerebral Vascular Diseases

There is an increased risk for intracerebral and subarachnoidal hemorrhages in chronic alcoholism with severe neuropsychiatric symptomatology depending on location and size. The association with ischemic stroke is less clear. A more frequent complication is chronic subdural hematoma, often preceded by some sometimes minor head trauma. Symptoms can initially be very mild or even missing. Headache is the most frequent symptom.

Central Pontine and Extrapontine Myelinolysis

A rare complication of alcoholism. A very rapid substitution of hyponatremia, a common electrolyte imbalance in alcoholism, seems to be of special relevance for the development of the demyelination in the pons or some other areas of the brain. Following clinical symptoms are severe with a high mortality: tetraparesis, cerebellar ataxia, bulbary symptoms, paresis of eye muscles, and central fever. The extreme form is a locked-in-syndrome with complete tetraplegia.

Marchiafava–Bignami Syndrome (Corpus Callosum Atrophy)

Another extremely rare disorder with poor prognosis and uncertain pathophysiology. In some chronic alcoholics, especially red wine drinkers in the Mediterranean, a necrosis of the corpus callosum and sclerosis of the cerebral cortex can lead to confusion, clouding of sensorium, seizures, and other neurological symptoms, coma, and death. If the patient survives, dementia is the most frequent outcome.

Tobacco–Alcohol Amblyopy

A bilateral affection (demyelination) of the optic nerve, chiasma opticum, and tractus opticus can lead to blurred or loss of vision. This rare syndrome can predominantly be found in heavy-smoking alcoholics with malnutrition. Tobacco smoke contains cyanides, which cannot sufficiently be detoxified in patients with severe liver dysfunction. They are believed to affect the optic nerve by free cyanides. Prognosis is rather poor.

Alcohol-Related Myelopathy

An extremely rare disorder with good prognosis. Alcohol myelotoxicity, malnutrition, and chronic liver damage can cause a progressive myelopathy with spastic paraparesis, neurogenic bladder dysfunction, and paresthesia.

Movement Disorders

Occasionally extrapyramidal symptoms, similar to Parkinson's disease, or dyskinesias can be seen in chronic alcoholics. The prognosis in abstinent patients is usually good. The more frequent essential tremor can be suppressed by small amounts of alcohol. This syndrome is not a result of chronic alcoholism.

Sleep Disorders

Alcohol consumption has major impact on the sleep architecture. Acute intake can lead to decreased latency to sleep onset, increased slow wave sleep, and decreased rapid eye movement sleep during the first half of the night. Insomnia is frequent during alcohol withdrawal and can persist long into abstinence. Other sleep disorders, e.g., sleep apnea syndrome, is usually worsened by alcohol.

Abstract

Alcohol use in normative samples becomes more prevalent and frequent across adolescence and early adulthood. This progression points to the facilitating role of consumption in resolving developmental tasks. In contrast, abuse is a relatively rare behavior and often has its roots in adaptation problems in childhood. Given the overall moderate or time-limited use among the majority, most consequences are immediate and circumscribed. Universal prevention efforts attempt to reduce the harm, or attempt to increase skills. In the cases where alcohol use is part of an enduring pattern of maladaptation, it is necessary to implement earlier selective intervention.

Alcohol use is prevalent among people beyond childhood and shows an intriguing association with age. Consumption increases rapidly across adolescence, shows a peak in the early twenties and declines gradually thereafter, once the major developmental tasks of emerging adulthood are resolved. Whereas young children disapprove of drinking, from adolescence on alcohol consumption is most often seen as signifying one's growing social maturity (i.e., in cultures with no absolute prohibition of alcohol use, e.g., for religious reasons).

The developmental-psychological perspective chosen departs from these observations and explains the emergence of alcohol use among the majority of young people as embedded in the normative psychosocial challenges of adolescence (Silbereisen and Eyferth, 1986). This period of the life span is characterized by growing attempts to find a particular place in life, which involves dealing with new social expectations and personal aspirations. The increasing interest at this time in novel and risky activities, and the unsupervised environments associated with them, probably also has neurobiological underpinnings related to the increase in dopamine input to the prefrontal cortex and limbic brain regions during early adolescence (Spear, 2013). Taken together, both viewpoints justify treating alcohol use among young people as a separate issue, distinct from alcohol use in general.

Abuse of alcohol is a relatively rare form of use, characterized by: (1) consumption over extended periods of time in situations which require clarity of perception and judgment; (2) drinking of even small amounts if decision making is impaired, due to developmental immaturity; (3) increasing the level of alcohol in order to compensate for declining psychoactive effects or to avoid malfunctioning; and (4) all forms of consumption which impair health or adequate mastery of normative exchanges with the environment (Newcomb and Bentler, 1989). Only a small subset of young people meets the clinical criteria for severe substance use disorders (e.g., APA, 2013; *see* Sexual Risk Behaviors).

Consumption Prevalence and Trends across Age

According to representative school surveys, such as the Monitoring the Future study in the USA (Johnston et al., 2013), the lifetime prevalence of alcohol use among 12th graders is of the order of 70% (in contrast, episodic heavy drinking (five drinks or more in a row) amounts to 24%). Even higher prevalence rates can be observed in many European countries (Hibell et al., 2012). Concerning frequency, two-thirds of 12- to 17-year-olds in a large German representative sample (BZgA, 2012) reported drinking less than once a month, about one-fourth up to several times a month, and the remaining 15% reported consuming alcohol on a regular basis, i.e., at least once a week (lifetime prevalence of alcohol use 73%). With regard to the quantity, these adolescent consume about 31 g pure alcohol per drinking occasion through alcoholic beverages. About 2% of the 12- to 15-year-olds and 13% of the 16- to 17-year-olds show a risky drinking pattern (more than 12 g or 24 g pure alcohol consumed on average at daily basis). These figures are in line with those that have been reported by the European School Survey Project on Alcohol and Other Drugs (ESPAD; Hibell et al., 2012) that regularly collects comparable data on substance use among 15- to 16-year-old students in nearly 40 European countries. For this age group, this study finds a prevalence of alcohol use for the past 30 days of 57% (87% lifetime prevalence) and an average of 45 g pure alcohol consumed on the last drinking day. In general, gender differences in consumption prevalence among the young are small but males are more likely than females to consume alcohol regularly and more often in higher quantity.

Beginning with the teen years entailing new freedoms and challenges, frequency and amount of consumption increase rapidly. According to a metaanalysis of more than 20 longitudinal studies (Fillmore et al., 1991), and more recent longitudinal studies (Chen and Jacobson, 2012; Paavola et al., 2004), the increase in frequency and quantity peaks in the early twenties, followed by a similarly sharp decline, particularly in frequency, which seems to be triggered by a general age-related trend toward conventionality (Jessor et al., 1991) and growing incompatibilities between consumption and new responsibilities as partner, parent, and worker.

Whereas countries like the US, Canada, and the UK share relatively moderate consumption, some Mediterranean and Eastern European countries rank much higher. In a longer perspective, consumption in industrialized countries increased dramatically after World War II, reaching unprecedented peaks

in the 1970s and 1980s, followed by stable or slightly declining figures thereafter (Silbereisen et al., 1995). During the past 20 years, prevalence rates of alcohol consumption decreased by about 20% in the US-American and European adolescents (Johnston et al., 2013; Hibell et al., 2012).

Immediate Negative Consequences for Well-Being

Due to the overall moderate and/or time-limited alcohol consumption among adolescents, most of the consequences for well-being are immediate. In general, a substantial minority sometimes experience discomfort, including feeling dizzy, hangovers, and headaches, primarily as a result of intoxication. Due to cultural differences in drinking habits (e.g., regarding a general acceptance of a 'culture of intoxication,' reflected, for instance, in speed drinking with peers in pubs), this experience is more common in Nordic countries in Europe (i.e., higher drunkenness rates, low risk perception of heavy use), in spite of higher consumption figures in the South.

According to data from the UK (Miller and Plant, 1996), between 5 and 30% of young people in midadolescence report problems associated with alcohol use in areas of social functioning such as personal adversities (reduced performance in school), social relationships (tensions with friends), sexuality (unwanted sexual encounters), and delinquency (trouble with police). The alcohol-related problems most often experienced by adolescent binge drinkers were accidents or injuries, physical fights, problems with friends or parents, and risky sexual behavior. More serious consequences (such as liver cirrhosis), in contrast, are very rare. However, especially early and/or high and frequent consumption can lead to physical or mental health problems (e.g., Boys et al., 2003), and about 44% of male and 17% of female adolescent regular drinkers met DSM criteria of alcohol abuse until age 34; 21% of men and 7% of women were classified as alcohol dependent (Wittchen et al., 2008). Alcohol is not a gateway drug, but it is certainly true that most users and abusers of other psychoactive substances begin with (and often maintain) the use of alcohol; however, they are also characterized by additional risks, such as family problems or deviant peer contacts (Kandel, 2002).

Risky sexual behavior and alcohol use correlate. This is probably not so much due to being uninhibited under the influence of alcohol but is rather rooted in common situational encounters, often concentrated in small subgroups, which may also share other risk factors such as mental disorders (APA, 2013; *see* Sexual Risk Behaviors).

As far as legal consequences are concerned, in spite of public concerns about the easy accessibility to alcohol for minors, there is little attempt at prosecution. In some countries the legal age for driving is considerably lower than that for alcohol drinking and purchase, which may exacerbate the problem of young people's reckless driving under the influence of alcohol. Recent empirical findings demonstrate that the rate of motor vehicle crashes among young drivers in the US had increased during the past decades. Risk of motor vehicle crashes among 16- and 17-year-olds was increased by driving at night, without adult supervision, together with passengers, being of male gender, and using alcohol (Rice et al., 2003). However, recently, alcohol use has lost its role as the main risk factor for motor crashes among teens, but not for drivers over the age of 20.

Differential Perspectives and Roles in Normative Psychosocial Development

Following an approach put forward by Moffitt (1993), a deeper understanding of the age trends, associations with biographical transitions, and immediate consequences of alcohol consumption can be achieved by distinguishing two sets of developmental antecedents and motives (APA, 2013). With regard to the adolescence-limited trajectory, which is characteristic of the absolute majority, alcohol use emerges because almost all adolescents must wait for the status and privileges of adults, despite their physical maturity, for several years (due to ever-expanding schooling, this gap is growing historically). Once they have resolved these issues, the frequency and intensity of problem behaviors, including alcohol, will vanish due to the influence of new environments that entail fewer opportunities and provide more deterrents concerning use. The life-course-persistent trajectory, in contrast, maintains consumption beyond the normative transitions to adulthood and is rooted in long-lasting problems of adaptation, starting in early childhood and encompassing neurological problems, attention deficit, impulsivity, and the like.

Moffitt's (1993) model is supported by various empirical findings. However, the risk factors for normative vs problematic trajectories of substance use across adolescence may vary by gender (e.g., Weichold et al., 2014). In addition, the model proposed by Moffitt matches well with more elaborate distinctions in the literature on alcohol and alcoholism where one of the subtypes is described as genetically influenced, with early behavioral malfunctioning, and embedded in a long-lasting antisocial personality disorder (e.g., Fitzgerald and Zucker, 2006; Tarter et al., 1999). Moreover, it also enables the remarkable covariation among alcohol use and other drugs, particularly externalizing problem behaviors to be understood. These problem behaviors, such as reckless driving or unprotected sexual activities, signify status for the young but are deemed inadequate by the community due to their precocity. Our general notion that it is the maturity gap which channels the alcohol use of the vast majority of adolescents sounds rather negative. Note, however, that most adolescents perceive alcohol as a means to ease social contacts and improve feelings in such contexts. Only a small minority drinks alcohol with the purpose of mood regulation when facing problems or coping with stress and boredom, whereas many adults do so (BZgA, 2012).

Alcohol is used by teens with regard to the formation of peer and romantic friendships, which are major developmental tasks in the second decade of life. Moderate consumption among those on the adolescent-limited trajectory corresponds prospectively to higher status and better cohesion within one's peer group, and is associated with a higher likelihood of romantic involvement. Moreover, adolescents seem to select leisure settings that offer opportunities for friendship contacts and provide alcohol in the right quantity and environment, such as discotheques, quite deliberately (Silbereisen et al.,

1992). In a nutshell, alcohol consumption may have constructive functions in healthy psychosocial development; for instance, by being a catalyst for the solution of developmental tasks in the majority of adolescents. For a minority, however, it may foreshadow a part of longer-termed maladaptation and problems in coping with challenges during adolescence (see also Schulenberg et al., 2000).

Universal and Selective Prevention Attempts

Given the almost normative use of alcohol among young people in many cultures, efforts aimed at prevention typically target responsible, self-controlled, and health-conscious use rather than abstinence. The multifunctional role of alcohol in the resolution of developmental tasks during adolescence and emerging adulthood represents the major pivot for primary prevention. Appropriate measures need to be undertaken early enough, that is, in late childhood/early adolescence, parallel to the first attempts to actually utilize the possible roles of alcohol consumption in the negotiation of the adolescent challenge.

Concerning measures on the proximal environmental level, one needs to reduce contexts, which entail schedules known to provoke the habituation of drinking, such as the episodic availability of large quantities in seducing locales (like 'binge' drinking in fraternity settings). Efforts most remote to the individual concern attempts to reduce national levels of per capita consumption in general, but curbing heavy drinking seems to affect consumption among the adult population, not the young. More specific measures try to minimize the harm by enforcing controls on the drinking settings, such as the establishment of licensing hours or by training bartenders to refuse serving alcohol to drivers in the UK.

The family is the proximal environment for most adolescents, which represents a major source of risk factors for drinking, such as parental modeling, inconsistency in rule setting, and a lack of developmental challenge. However, very few attempts at prevention on the family level exist to date (e.g., Mason and Spoth, 2012).

Concerning prevention at the individual level, targeting adolescents at school is the rule. Given the role of alcohol use in response to normative developmental difficulties, prominent universal programs targeting entire cohorts address general life skills, such as adequate self-perception, empathy with others, critical thinking, decision making, communication, sociability, affect regulation, and coping with stress (Botvin, 1996). Such life skills are supposed to facilitate the solution of everyday challenges related to the completion of developmental tasks (WHO, 1997).

In addition, as revealed by recent metaanalyses of evaluation studies (e.g., Hansen et al., 2010), the most successful programs are characterized by a combination of skills and attitude development, promotion of bonding to norm-transmitting contexts, and the promotion of resistance skills, positive within-classroom interactions, and positive peer relationships within a context of high social support. In addition, within successful programs, adolescents are actively involved, and they practice skills; for instance, in role-plays representing age-typical challenges (e.g., how to resist unwanted offerings of alcohol by peers). These characteristics are best reflected by the life skills approach. Empirical studies using such programs demonstrated short-, and, at times, longer-term positive effects (e.g., Weichold, in press). Thereby, it is important not to expect sustainable effects unless intervention takes place repeatedly at major milestones during adolescence and beyond.

Concerning the life-course-persistent trajectory of alcohol use, prevention as described would begin too late and is sometimes inefficient (and may even hurt those on the adolescence-limited trajectory due to heightened contacts with negative role models). Rather, prevention would need to start at a much earlier age, and would need to address directly the associated early childhood problems such as impulsivity.

Alcohol Use and Abuse

Abstract

Alcohol is consumed widely in almost all except Islamic countries of the world. Consumption levels vary widely by region and within individual countries, although generally higher levels of consumption can be found in more developed, higher income, and European countries. The negative consequences of alcohol 'misuse' can include short- and long-term health and social problems for drinkers, and for their families and wider society. Such problems are further shaped by multiple socioeconomic and contextual factors. The widespread yet complex nature of these problems means that a basic understanding of both alcohol misuse and brief interventions is essential for social workers.

Introduction – The Cultural Context to Consumption

The consumption of psychoactive drugs has been a feature of almost all societies, cultures, and tribes across humanity, although the types of substances, motivations for use, and the social controls that surround their use have varied considerably between different societies, historical periods, and cultural groups (Coomber and South, 2004). For some substances their use is condemned and criminalized, whereas for others there are degrees of social or legal acceptance. Motivations for use have ranged from the religious to the recreational. Alcohol, along with caffeine and tobacco, is a drug which has been widely used and socially accepted in most societies around the world for centuries, and is at the heart of many religious ceremonies, festivities, and social celebrations. The brewing and fermentation of alcoholic beverages from plants can be traced back to 5000 BC and the distillation of spirits to the AD ninth century. While alcohol use is outlawed in a handful of Islamic countries, in most countries it is legal to consume alcohol, although restrictions exist relating to aspects of the manufacture, promotion, sale, and consumption of alcoholic drinks, discussed further below. As Rehm et al. note (2003: 154) "with the exception of Islamic regions, alcohol is ubiquitous in the modern world." This article examines alcohol consumption, the problems following its use, and concludes by raising issues for social work practice.

Global Patterns of Consumption

There are enormous differences in alcohol use both within countries and between countries. The World Health Organization produces Global Status reports on alcohol and health which provide a comprehensive picture of patterns of international, national, and regional alcohol consumption along with health consequences and policy responses. One key way of comparing consumption levels around the world is to calculate the average per capita consumption of alcohol, usually measured in terms of liters of pure alcohol or ethanol consumed per year. In the most recent Global Status report (WHO, 2011), worldwide consumption of alcohol by people aged 15 and over was calculated to be 6.13 liters in 2005, ranging from 0.65 liters in the Eastern Mediterranean up to 12.18 liters in Europe.

Pakistan, an Islamic country where alcohol sale and use is illegal, has one of the lowest per capita consumption levels of 0.06 liters per annum, with drinking concentrated in higher income and secular groups, where it is seen as aspirational. By contrast, Russia has one of the highest per capita consumption levels at 15.7 liters, with two-thirds of alcohol consumption being of spirits and particularly vodka. By excluding abstainers from this total, per capital consumption among Russian men is estimated to be 35.38 liters of pure alcohol per annum (WHO, 2011). In the UK recorded per capita consumption was estimated at 10.2 liters of pure alcohol per person aged 15 years and over in 2010 (Gilmore et al., 2013), a slight fall on earlier years. If an estimate of 10% for unrecorded consumption is included (such as duty-free purchases and home-brewed alcohol) and further accounting for at least 10% abstainers in the UK, consumption increases to 12.3 liters per drinker, in line with the European average and about twice the global average. This translates to 1217 units of alcohol per year, or 23 units per person per week, which is higher than the recommended upper limits for low-risk consumption both for women and men (Shield et al., 2013).

Global alcohol consumption levels have been relatively stable since 1990, with a decline in the 1970–90s in some wine drinking countries and an increase in the 2000s in some Islamic regions. However, there are large differences between countries in terms of abstention rates, with higher numbers of drinkers in higher income countries in Europe and North America, and lower numbers of drinkers in North Africa and South Asia where there are greater numbers of Muslims in the population. Abstention is also higher among women than men. Given the large differences in the percentage of regular drinkers in countries around the world – from only a third in Jamaica up to 90% in some European countries (WHO, 2011) – the calculation for average per capita consumption can be modified by excluding abstainers to more accurately reflect average national consumption rates among drinkers.

Per capita consumption is further considered an underestimate of individual drinking because in many regions,

particularly in developing countries, the unrecorded production of homemade or illicit alcohol makes a significant contribution to total alcohol consumed, particularly if controls on legally produced alcoholic beverages are perceived to be too stringent. As the studies in Haworth and Simpson's (2004) international collection explore, the primary driver in the production and consumption of illicit alcohol is poverty. Illicit alcohol can have significant health risks resulting from its variable strength, lack of quality control, and potential contaminants, further compounding the health risks of legal alcoholic beverages (discussed below), although Haworth and Simpson suggest that high profile media coverage has sensationalized what can be exceptional events.

Types of Alcoholic Beverages

There are regional variations in types of alcoholic drinks consumed which reflect the climatic, geographical, and topological features conducive to cultivation of the various fruits and grains utilized in brewing and distillation processes. In general, just under half of total recorded alcohol consumed is of spirits, particularly favored in the Middle East and Asia, a third of alcohol consumed is beer, favored in the Americas, and under one tenth is wine, particularly in Europe. Another tenth takes the form of fermented grains and fortified wines, mostly in African countries (WHO, 2011).

Within Europe, drinking patterns have been characterized as 'dry' in northern European/Protestant countries and 'wet' in southern Mediterranean/Catholic countries. In the north, a pattern of heavy episodic drinking of beer and spirits with friends in bars at weekends and celebrations has predominated whereas in the south, alcohol consumption is characterized as more moderate, frequent, and integrated into daily family life, with wine consumed with meals throughout the week at home. Historically, it is the northern and north-western European and Scandinavian countries that have been associated with excessive consumption and public drunkenness (Jarvinen and Room, 2007). These traditional patterns of consumption have been changing in recent years, however, with growing popularity of European-style lagers and spirits among young people alongside a reduction in wine production and consumption, counterbalanced by a move to idealize southern European wine drinking cultures as producing more integrated and less problematic consumption, supported by various licensing initiatives and urban regeneration programs at local and national level (Jayne et al., 2008). Room and Makela (2000) have further elaborated on this 'wet' versus 'dry' dichotomy in their typology of drinking cultures. They identified four types of drinking cultures – abstinent, constrained ritual drinking, banalized drinking, and fiesta drunkenness – based on combining frequency of drinking with drunkenness. A more recent study of European drinking patterns by Makela et al. (2006), however, suggests that there were no clear differences between countries or regions, a situation further complicated by the influences of gender and age, so that regional variations are becoming less pronounced among younger generations with no country exhibiting an 'ideal' type of drinking culture.

Understanding Alcohol Abuse

The 'use-misuse-abuse' typology is a spectrum which characterizes the degrees of social acceptability of consumption of any psychoactive substance and distinguishes between legitimate, medically or socially sanctioned use (for example, medication from a recognized health practitioner); misuse where consumption is unsanctioned or illegitimate; and abuse where problematic use results in harmful consequences for the individual or society. Therefore, the term 'misuse' recognizes that (moderate) 'use' can be socially acceptable and prosocial in function, yet also allows for the possibility of unsanctioned or problematic use. In this article, a broad definition of alcohol abuse is utilized to cover the full range of drinking problems including harmful and dependent drinking.

The negative consequences of alcohol 'abuse' can include short- and long-term problems for drinkers, and for their families, communities, and wider society. Such alcohol-related problems are further shaped by multiple socioeconomic and contextual factors which, as young people grow up and start to drink, include the influences of parents, siblings, peer networks, and levels of family cohesion and support, as well as factors relating to the marketing and promotion of alcohol (Velleman, 2009).

While in many societies, moderate drinking is seen as both legally and socially acceptable, and for individual drinkers it can be associated with pleasurable and sociable leisure time experiences, for a small minority of drinkers problems can develop. How we define, measure, and explain such alcohol-related problems are themselves influenced by the historical and cultural context within which people are living, as well as differences within socioeconomic, cultural, religious, and demographic groupings. However, some broad observations are possible on the consequences of alcohol and abuse, relating to alcohol-related problems for individual drinkers and wider society.

Health Problems

The World Health Organization describes alcohol as 'one of the world's leading health risks' (2011: 20) linked to over 60 major diseases, accounting for 4.5% of the global burden of disease and injuries, and resulting in the premature death of 2.5 million people (4% of all deaths) each year. Among men aged 15–59, alcohol is the leading risk factor for death. Alcohol-related health problems can be both acute and chronic and are directly affected by not only the average volume of alcohol consumed but also patterns of drinking (Rehm et al., 2010). Acute harms result from intoxication produced by heavy episodic drinking rather than overall consumption levels, resulting in injury, road traffic accidents, poisoning, and sudden cardiac death (Rehm et al., 2003). Unintentional injuries alone account for 30% of all alcohol attributable deaths globally (WHO, 2011). However, the majority of health problems relate to chronic harm, produced by the cumulative effect of repeated drinking beyond recommended levels, resulting in liver cirrhosis (17% of alcohol attributable deaths), increased risk of other serious illnesses including various cancers (22% of attributable deaths), and cardiovascular

diseases (14% of attributable deaths). Up to half of all liver cirrhosis is attributed to alcohol (WHO, 2011). Dependent drinking – defined as repeatedly drinking beyond the sensible drinking guidelines recommended by health advisors and resulting in signs of physical or psychological dependence such as daily drinking, a compulsion to drink, increased tolerance, and a recognized withdrawal syndrome if attempting to stop – is particularly linked to these long-term health problems.

The extent to which drinking alcohol in moderation may offer cardiovascular protection has been debated intensely in recent years, with health professionals and alcohol industry representatives pitted against each other regarding the evidence base for such claims. There are exceptions of course. For example, it is recommended that pregnant women avoid alcohol as there is risk to the fetus. Drinking prior to operating machinery or driving a vehicle is actively discouraged and there is growing concern about the impact on not only the adolescent but also the young adult brain. The physical implications of alcohol misuse are well documented and include increased risk of liver cirrhosis, hepatitis, gastritis, pancreatitis, various cancers, nutritional deficiencies, obesity, diabetes, gout, cardiomyopathy, raised blood pressure, cardiac arrhythmia, strokes, brain damage, neuropathy, acute alcoholic poisoning, and impotence as well as insomnia, depression, anxiety, and amnesia, to name just a few. Damage can occur on both a physical and mental level. Indeed, there is a close link between alcohol dependency and mental health problems, including incidents of suicide. However, alcohol is part of a complex causal web of health and social problems, which makes the causal role of alcohol difficult to disentangle (Babor et al., 2003).

What does seem to be accepted, however, is that the global burden of alcohol-related disease will increase. This is because firstly, increased volumes of alcohol are being consumed in the two largest countries in the world (China and India) associated with their rapid economic development and social change; and secondly, globalization and alcohol advertising is leading to a convergence of drinking patterns. There has been a decline in the southern Mediterranean model of moderate drinking with meals and an increase in heavy episodic drinking as part of a young adult partying lifestyle which characterizes the northern European model (Rehm et al., 2003).

Social Problems

Alongside the health problems associated with alcohol abuse, there is a significant global burden associated with the social harms of alcohol. Social problems which can be attributed directly to alcohol include public drunkenness, disorder, and aggression, although alcohol's role in other social problems, as with many health problems, may be contributory rather than causal (Babor et al., 2003). Both heavy episodic drinking and dependent drinking can have a negative impact upon the health and well being of families, partners, and the wider social sphere of a problem drinker, with alcohol a contributory factor in stranger violence (for both offenders and victims), domestic violence or partner abuse (Hall, 2011), and child neglect and abuse. Intentional injuries account for 12% of all alcohol attributable deaths globally (WHO, 2011). There is also the indirect negative impact of alcohol dependency on significant others. It has been estimated that the stress, pain, and suffering resulting from drug and alcohol addiction impacts upon approximately 100 million family members worldwide (Orford et al., 2013). Finally, the economic impact of alcohol and abuse, measured in terms of lost productivity and absenteeism from work due to accidents, illness, and injury, has been calculated at £6.4 billion in the UK alone (PMSU, 2004).

Heavy Episodic Drinking: From Benders to Binges

At a global level, just over one in ten drinkers have had heavy drinking episodes on a weekly basis during the previous year (WHO, 2011). Heavy episodic drinking tends to be higher in higher income countries but is not necessarily directly related to high alcohol per capita consumption levels. So, for example, there are lower alcohol consuming countries such as some African and South Asian countries (e.g., India and Malawi) where there are high levels of heavy drinking among those who do drink. By contrast, there are some higher alcohol per capita consumption countries such as European wine drinking countries with regular but moderate consumption patterns (e.g., France) where heavy episodic drinking is relatively low.

While the term 'binge' was originally applied in clinical practice to refer to extended drinking resulting in the suspension of the drinker's usual daily activities for a day or more (also called a 'bender'), in the early 1990s American researchers applied the term to heavy consumption during a limited time period (Wechsler and Austin, 1998). In the two decades since then concerns have mounted regarding heavy episodic consumption. Indeed, as noted above (e.g., Rehm et al., 2010), heavy episodic drinking is associated with a range of negative health and social outcomes. However, there are considerable international variations in health advice regarding what could be considered a 'safe' or 'sensible' limit to alcohol consumption, either per drinking session or per week, and what could be considered a 'binge.' For example, in the UK a 'binge' is usually defined as drinking more than double the recommended maximum daily 'sensible' consumption levels in a single drinking session (Department of Health, 1995) of four units of alcohol for men and three units of alcohol for women, known as the 8/6 unit measure. Thus, a man consuming 64 g of alcohol and a woman consuming 48 g of alcohol would be classified as binge drinking. By contrast, in the USA a man would need to drink 70 g of alcohol and a woman 56 g to be classified as binge drinking.

While overall consumption levels have remained relatively stable since 1990 (WHO, 2011), a key change in this period has been an escalation in the quantity of alcohol consumed in a drinking episode, particularly by young people, and an associated increase in drinking to intoxication resulting in changing alcohol-related attitudes as well as behaviors, with a 'normalization of determined drunkenness' in the early twenty-first century (Measham, 2004: 321). This change in consumption patterns has been noted across most continents of the world, but is particularly pronounced in Europe (Jarvinen and Room, 2007). The reasons for this increase in 'binge' drinking can be linked to developments in the alcohol industry, as well as broader changes in the nature of adolescence, young adulthood, and leisure lifestyles in late modern

societies. In relation to young adults of drinking age, it has been suggested that a 'new culture of intoxication' emerged from the 1990s onward (Measham and Brain, 2005) which was linked to changes in licensed leisure venues and the associated expansion of the 'night time economy' (Hobbs et al., 2003).

Female Drinkers

More recently, concerns about drinking, public drunkenness, and health problems have shifted from young people toward women, particularly professional women. While heavy episodic drinking is much more common in men than women (WHO, 2011), and in boys than girls (Hibell et al., 2009), nevertheless in many countries women's consumption has increased at a faster rate than men's, if not yet on a par. This has led to suggestions that we are seeing a gender convergence at least in some countries (Bloomfield et al., 2001), driven by socioeconomic change including women's increased educational and employment attainments and associated increased disposable income, alongside advertising campaigns, promotions, and broader media coverage directed at female drinkers. This can be illustrated in the narrower gender differences in northern Europe than southern Europe, for example, with the frequency of heavy episodic drinking by northern European young women and young men showing the least marked gender difference of the various drinking variables under consideration (Makela et al., 2006).

Responses to Alcohol and Abuse: Population Level Policy Responses

Pricing

At population level, a strong evidence base supports the existence of a relationship between price and consumption, including influential modeling work conducted by researchers at the University of Sheffield (Meng et al., 2012) and from recent Canadian research (Zhao et al., 2013) which concluded that each percent increase in price results in a decrease in alcohol-related problems. Similarly, Ogilvie et al.'s (2005) synthesis of 30 reviews, including seven systematic reviews, concluded that a 10% increase in price in licensed premises reduced demand for beer by about 5% and by about 10% in off licenses. It is clear that the most efficient way to reduce alcohol-related problems at population level is to increase the taxation of alcoholic drinks. However, due to tensions between the interests and preferences of state, industry, and individual drinkers, alternative suggestions have included minimum unit pricing and graded differential taxation on alcohol by volume strength of alcoholic beverages, as well as differential taxation by beverage type to encourage the production of regional and heritage products, such as cider in the UK.

Availability

Restrictions on availability – such as restrictions on trading hours, density of outlets, types of alcoholic beverages sold, and particularly minimum purchase age – can be effective in reducing alcohol-related problems at population level. Brand et al. (2007) found that in general the stronger the alcohol control policy in any given country, the less people seemed to drink, although this was also mediated by the cultural context within specific countries. Other interventions at population level of lesser efficacy include restrictions on advertising and promotional practices, with impact dependent on both the degree of enforcement and whether voluntary industry self-regulation or state regulation. As with other areas of behavioral change such as banning smoking in public places or the introduction of mandatory seat belts for motor vehicle passengers, a key issue is effective enforcement.

Responses to Alcohol and Abuse: Health and Social Services and Individual Behavior Change

Early and brief interventions in primary care with problem drinkers can be effective. For some people at certain points in their lives, treatment for drinking problems can save lives and help facilitate change (NICE, 2013), while others are able to change their drinking behavior without any formal help (Klingemann, 2004). Indeed, some researchers suggest that individual drinkers 'grow out' of problematic use, with periods of 'excessive appetite' followed by the reassertion of self-control and 'normal' everyday life (Orford, 1985). Such change can occur quickly or slowly (Laudet and White, 2008); as part of the maturation process or triggered by changes in a person's life (Barrie, 2012); and without planning or as part of a carefully formulated strategy (Bischof et al., 2000).

A negative drinking experience or a reappraisal of the risks can lead to a rearrangement of the cognitive framework through which a person explains his/her drinking to him-/herself. The emergence of new perspectives which challenge previously held assumptions becomes a forerunner to change (Raistrick et al., 2006). This process can cause cognitive dissonance – an uncomfortable state of mind where a drinker is wrestling with two conflicting ideas or a discrepancy between his/her self-image and his/her behavior (Hohman, 2012).

While people with drinking problems may vacillate at the prospect of change, such ambivalence is normal although it can reduce motivation (Wagner and Ingersoll, 2013). Change holds the promise of benefits but it also involves loss and therefore it can provoke conformist 'comfort-zone' impulses (Miller and Rollnick, 2013). Understanding that ambivalence toward change is normal helps to make sense of the apparent reluctance of people with alcohol problems to act in ways which seem to be manifested in their best interests. Change may bring better health, the promise of a job, and avoidance of the criminal justice system but it can also mean losing a specific social life (Barrie, 2012). For some, change will bring the anxiety-provoking prospect of dealing with physical withdrawal. Where a person's identity is firmly bound up with drinking, a change in direction may entail a profound shift in their sense of self (White, 2012).

Prochaska and DiClemente's (1984) cycle of change suggests that people progress through six distinct stages:

- Precontemplation: the person either does not consider that they have a problem or has no intention of addressing it at this point;
- Contemplation: the contemplator has yet to take action but has begun to give serious consideration to the need to do so. Ambivalence is the hallmark of people in this stage;

- Preparation: the person has committed themselves to the idea that action is necessary and will be formulating what they should do;
- Action: the person alters their drinking behavior in significant ways and makes environmental and other changes which support this;
- Maintenance: this is not a static phase but one where the person acts to sustain the changes made and to avoid relapse;
- Relapse: a return to the previous behavior.

For health and social services, this cycle of change provides a relatively simple framework to address alcohol misuse (Thompson, 2009). However, the idea that people move consecutively through discreet stages has been questioned and some people make change without appearing to pass through the preparatory stages. Despite such criticisms, however, the popularity of the cycle of change suggests that it strikes a chord with alcohol services and service users alike (Paylor et al., 2012). While its limitations indicate that rigid application should be avoided, it provides a common sense framework which brings together a number of key themes including the centrality of motivation, ambivalence, and commitment to change.

Social Work Practice

More broadly, responding to alcohol use is a necessary part of many social workers' jobs, whatever their specialist area of practice. Social workers' knowledge of alcohol does not have to be comprehensive, but they do have to have enough to feel confident to ask the right questions and offer basic advice or brief interventions. Alcohol use cuts across areas of social work practice and does not discriminate according to gender, age, social class, ethnicity, or disability. Service users have a right to a social work service that is prepared for and committed to helping them change their problematic alcohol use.

Increasingly in many countries, however, it is specialist third sector organizations rather than the statutory sector that address alcohol-related problems, some of which have restricted or partisan approaches to what can be a politically and socially contentious problem. Most recently there has been an ideological shift in interventions and treatment in developed countries with the growth of 12-step fellowship programs and the development of a 'recovery movement' resulting in a shift from harm reduction to abstinence-based recovery. The ideological appeal of abstinence-based recovery programs and zealousness of some participants, as well as the contested evidence base for their efficacy, has led to fierce contemporary debate. In response to this, the concept of 'recovery' now focuses not only on overcoming alcohol or drug dependence, but is a much wider and more holistic notion which encompasses the achievement of positive outcomes in relation to health and well-being, educational and employment achievements, as well as personal relationships, and finances (ACMD, 2013).

Conclusion

Alcohol is a legal substance, widely available, not prohibitively expensive and contributes significantly to state economies in the form of employment and taxation receipts. Its use is not only condoned by most societies, but regarded as an important feature of family and social life. We have seen changes in the amount consumed, the consumers, and the products which they consume. There are various definitions of alcohol use and misuse ranging from those that are more physiologically based to those that are socially based. Different studies use different terminology, including 'heavy drinking,' 'dependence,' 'misuse,' and 'abuse' as well as 'problem drinking,' and 'binge drinking.' Such terms frequently overlap in the literature, with no common definition and minimal explanation of the criteria used to measure the behavior that gives cause for concern. However, there does seem to be consensus that what is being described and studied is the consumption of alcohol that warrants attention because it repeatedly, seriously, and negatively affects the drinker, their family, and wider society.

It is clear that alcohol abuse affects not only the individual but also those people around them. Problem drinking is an issue that cuts across many boundaries and impacts upon a wide range of agencies. The treatment of alcohol depends upon the philosophical perspectives of the individual and indeed the agency providing the assistance. Some suggest that problem alcohol use is a disease with a genetic disposition. Those that take this physiological approach would argue that the likelihood of becoming an 'alcoholic' is much more determined by genetics than by social environment. Others see periods of alcohol misuse as part of a maturation process and a symptom of the wider struggle between greater and lesser self-control within 'normal' everyday adolescent and adult life. Still others view drink problems as essentially social, cultural, and psychological in origin. This approach seeks to educate and empower the problem drinker by concentrating on the identification of triggers, insight into high-risk situations, the development of relapse prevention strategies, and positive self-talk. They suggest that five key stages exist, though not necessarily in any order (Precontemplation, Contemplation, Preparation, Action, and Maintenance), and believe that it is possible for health and social service professionals to intervene at any stage, provided the stage has been properly identified. Regardless of these various approaches to the problem, what is clear is that the scale and ubiquity of alcohol-related problems means that many social workers will encounter alcohol misuse in their workloads and therefore an understanding of both alcohol misuse and the potential of brief interventions and motivational interviewing to support change is essential for contemporary social work practice.

Abstract

Jeffrey C. Alexander is a social theorist and cultural sociologist. This article describes Alexander's intellectual developments and professional achievements, from his undergraduate days at Harvard University through to the present. Four threads of Alexander's intellectual pursuits are discussed, including his contributions to sociological theory, his development of the strong program in cultural sociology, his engagement in political and social theory and the publication of *The Civil Sphere*, and, finally, his recent contributions on the topics of social performance and iconicity.

Jeffrey C. Alexander is a social theorist and cultural sociologist. With the publication of his doctoral thesis as a four-volume series, titled, *Theoretical Logic in Sociology*, he established himself as a promising new voice in American sociological theory, and took a considerable step toward becoming one of the most influential social theorists in the world. Since the publication of these volumes, Alexander has helmed intellectual movements in neofunctionalism and cultural sociology, theorized and empirically reconstructed the American civil sphere, and engaged in a series of interventions into subjects ranging from social performance, to cultural trauma, to iconicity, and to events as varied as US presidential elections and Egypt's performative revolution. His work is characterized by theoretical sophistication and philosophical musicality, elegant and authoritative prose, an adventurer's openness to interdisciplinarity, and a commitment to maintaining the centrality of meaning in representations of social life.

Alexander was born on 30 May 1947 in Milwaukee, Wisconsin, to Frederick Charles Alexander and Esther Leah Schlossman Alexander. His father worked in advertising, and his mother, who earned a Master of Arts in Social Work from the University of Wisconsin, Milwaukee, stayed at home to raise the couple's two sons and later worked for the Visiting Nurses Association of Los Angeles. Jeffrey's younger brother, Charles 'Skip' Alexander, earned a PhD in psychology from Harvard in 1982, and was a leading figure and published extensively on the intersections of developmental psychology and meditative philosophies and practices.

Jeffrey attended public high school in Los Angeles, California, and in 1965 entered Harvard as an undergraduate in the university's Committee on Degrees in Social Science program. Alexander's intellectual trajectory and writing acumen were formed in the milieu of an interdisciplinary education in political theory, literature and drama studies, and moral and political philosophy. He contributed regularly to the *Harvard Crimson*, participated in New Left study groups, and participated in movement organizations like the Students for a Democratic Society.

A self-described Sixties communard, Alexander's formative intellectual identity took inspiration from representatives of the cultural Marxism of the day, and he identified more with the Marcuse, Gramsci, and Sartre types than voices of the more orthodox, economistic variety (2005: 40–42). Actively engaged in student political culture, writing for the university newspaper, and studying literary, political, and critical theory, Alexander accumulated intellectual ingredients and scholarly practices that would become hallmarks of his future academic career: a command over a broad range of intellectual movements, a disciplined approach to writing, and a commitment to emphasizing and honing analytical tools for apprehending the meaning structures that constitute and order social existence.

Despite having taken but a few social science courses at Harvard, which included a sociology course in his final year taught by the towering figure, Talcott Parsons, Alexander decided to pursue a PhD in sociology and entered the University of California, Berkeley's program in 1969.

Alexander continued to engage in political activism during his first few years at Berkeley. Yet with sectarianism splitting the radical Left, Nixon's backlash politics winning the American political center, and with his interests shifting toward intellectual pursuits, Alexander turned to his studies and to more diverse, or classical and modern, sources for illumination than the Marxism that had shaped his early intellectual self.

Alexander gravitated toward theory courses at Berkeley. He took a year-long sociological theory seminar helmed by Neil Smelser, twice, and immersed himself in Durkheim's work in a course taught by Leo Lowenthal. Robert Bellah had just published his influential essay, 'Civil Religion in America' (1967), and this article as well as Bellah's interests in symbolism, Durkheim, and Weber, and his friendship with anthropologist, Clifford Geertz, shaped Alexander. In addition to contributing to Alexander's knowledge of sociological theory, these three figures, Bellah, Lowenthal, and Smelser, served as members on his doctoral thesis committee. Lowenthal represented a connection to Alexander's early interest in cultural Marxism; Bellah cultivated Alexander's interest in symbolic realism; and Smelser, a leading role in extending Parsonian functionalism, and the personification of theoretical precociousness and youthful prodigiousness, left a mark on the young Alexander as well.

Alexander started an Assistant Professorship in sociology at the University of California Los Angeles (UCLA) in 1976 and received his PhD from Berkeley in 1978, and the *Theoretical Logic* volumes were published in 1982–83. He was promoted directly to a full professorship at UCLA in 1981. He remained at the university for the next 20 years, during which he served in multiple capacities, including as Department Chair from 1989 to 1992. An institutional entrepreneur, Alexander helped build

the UCLA sociology program into one of the most diverse, eclectic, and highly ranked programs in the United States during his tenure.

Also while at UCLA, beginning in 1984, Alexander formed a discussion group with graduate students interested in investigating culture in society, which adopted the moniker the 'Culture Club.' Alexander and an impressive series of graduate students took the cultural turn together and, over the subsequent three decades, built a body of publications that constitute the core of a perspective that Alexander named (invoking David Bloor and colleagues' strong programme in the sociology of scientific knowledge) the 'strong program in cultural sociology.' Alexander moved to Yale University in 2001, where he became Lillian Chavenson Saden Professor of Sociology, and where he resumed institution building. He served as Department Chair from 2002 to 2005 and helped revitalize the program, which was undergoing a challenging period of transition. Also upon arriving at Yale, Alexander formally institutionalized the 'Culture Club' by launching the Center for Cultural Sociology, which he codirects with Yale sociology colleagues Ron Eyerman, Philip Smith, and as of 2013, Frederick Wherry.

A public sociologist in many senses of the phrase, Alexander has deep connections in the field and a vast network of colleagues on whom he has drawn for intellectual, collegial, and personal inspiration and support. In addition to contributing to Alexander's intellectual and professional development, Neil Smelser and the recently deceased Robert Bellah played central roles in the middle and later stages of Alexander's career, and Alexander cites both as representing important exemplars of academic, intellectual, and personal integrity to him over the duration of his career. Alexander has also acknowledged Nicholas Entriken, Ron Eyerman, Roger Friedland, Bernhard Giesen, Steven Seidman, Piotr Sztompka, and Kenneth Thompson as colleagues who have challenged, inspired, and supported him over the course of his career.

Since the mid-1970s, Alexander has been extraordinarily prolific, and discernible threads run through the articles and books he has produced during the four decades of this most productive and creative of careers.

Theory

In the earliest thread Alexander wove into what would become his oeuvre, he adopted an unpopular and antagonistic stance by making the centerpiece of his ambitious intellectual project the then besieged and decidedly unfashionable legacy of Talcott Parsons and the Parsonian structural functionalism that dominated mid-century American sociology. A backlash against Parsonianism was in full sway in 1960s and the 1970s American sociology, propelled by critical theorists arguing that Parsons had neglected conflict, power, and a pervading instrumental rationality, on the one hand, and by microsociologists or symbolic interactionists arguing that Parsons's structuralism neglected the micro, interactional sources of social order and the creative, strategic dimensions of individual actors, on the other. While Alexander appreciated the Parsonian project, his aims in this initial phase transcended Parsons's, and were motivated toward legitimating a postpositivist understanding of theory and social science, advocating for multidimensionality in social scientific endeavors, and in rescuing voluntarism from theory's determinisms.

Alexander opens the *Theoretical Logic* volumes by offering a schematic of the structure of scientific thought. The elemental components of this thought compose a continuum, ranging from the abstract, theoretical pole on one end, to the empirical, 'factual' pole on the other. On the theoretical side lie presuppositions and ideological orientations that characterize assumptions about the originating sources of social action and order, while the empirical pole is composed of issues of empirical testing and measurement, methods, and observations of the factual world. Between these two poles lie intermediate levels of scientific frameworks such as formulations of concepts, definitions, and laws.

From this model Alexander makes several points about the practice of social science: these poles cannot and do not operate independently of one another. Be it deductive, theory-driven science or inductive, model building from observation and facts, scientific representations demonstrate assumptions about both poles on the continuum. "Theory cannot be built without facts," he states in a recapitulation of his argument in *Twenty Lectures* (1987: 5), "but it cannot be built only with them either." Alexander's version of postpositivism argues that social scientists should be reflexive regarding how each pole informs, shapes, and constitutes the other, as well as the dimensions that lie between.

Alexander also argues that all social scientific theories contain, and indeed must contain, assumptions, if not explicit statements, regarding two core dimensions of the social; namely, they must contain characterizations about the nature, origins, and sources of both social action and social order. Presuppositions about social action demonstrate assumptions that people act according to one of two logics, or that social actions are born primarily of rational or nonrational sources and motives. Rational models of action portray actors as generally selfish, as acting to maximize efficiency, and as responding to forces outside of one's self. Nonrational models, by contrast, emphasize that people are motivated by internal sources that are normative and/or moral in nature, or based on emotions and unconscious desires. In terms of the production of social order, or the regularity of patterns in social life, sociologists presuppose either individualistic sources or collectivist sources. Individualistic formulations of order acknowledge that supraindividual patterns appear to exist, but these formulations emphasize that they result from individual choice and negotiation, and are based on considerations made in real time. Collective formations, in comparison, focus on patterns and structures that exist regardless of and prior to any specific individual experiencing them.

In advocating for multidimensional approaches to doing sociology, Alexander argues that tight adherence to either side of the action and order dichotomies produces reductionistic, one-dimensional interpretations whose explanatory powers are weakened because they sacrifice the influence and power of the alternative positions. One-dimensional explanations produce residual categories – or sites, phenomena, or processes – that, since they do not fit into the logic of the dominant explanatory model, must be addressed in ad hoc and oftentimes contradictory ways.

Alexander concludes by dismissing individualistic approaches to order, arguing that they make the very problem

of order itself a residual, or unexplained, category; he does acknowledge, however, that individualistic approaches have revealed important dimensions of some empirical processes. Social action, he concludes, neither should be reduced to either instrumental or normative characterizations, nor should it be conceived as ordered by either internal or external structures; social action should be conceived as composed and motivated by all these sources (1982a: 123).

Over the course of the next three volumes, Alexander analyzes and reinterprets Marx, Durkheim, Weber, and Parsons's bodies of work in terms of their approaches to the problems of action and order. Durkheim and Marx, both with collectivist approaches to order, move in opposite directions over the courses of their intellectual careers, Alexander argues. Action in Marx's mature writing became rigidly rational, mechanistic, instrumental, and strictly materialist in contrast to the more voluntaristic and nonrationalist formulations that characterized writings from his earlier, more Hegelian-inspired output. While the young Durkheim's response to the questions of action was more ambiguous, it nonetheless demonstrated strong materialist assumptions. As he matured, however, Durkheim's formulations of action became increasingly idealist and voluntaristic, and matched the mature Marx in terms of his adherence to a one-dimensional approach to the issue. Weber, on the hand, represented an important while incremental and inconsistent move toward multidimensionality. While Alexander sees instances of multidimensionality in Weber's writings on religion, particularly in his treatment of the protestant ethic, as well as in his methodological essays, far more often Weber's work is characterized by one-dimensional moves into either the materialist or idealist camp, and in Alexander's view, it is most often grounded in materialist formulations (e.g., Weber's political writings in *Economy and Society*). It is in the work of Talcott Parsons, Alexander finds that sociological theory has realized its most faithfully multidimensional framework to date.

The publication of the *Theoretical Logic* volumes drew enormous attention, and produced a considerable number of both critical and laudatory reviews. All acknowledged the enormous ambition, scope, thoroughness, and creativity of Alexander's achievement, however, and these publications established Alexander as one of the leading sociological theorist of his generation.

Under the rubric of neofunctionalism – named, in effect, to suggest an alternative to the era's neo-Marxism – Alexander, frequently collaborating with one of his first graduate students, Paul Colomy, spent over a decade critically reenvisioning Parsons's work, acknowledging its weaknesses and contradictions, and articulating theoretical avenues for navigating beyond its limitations. Even after declaring that the neofunctionalist project had come to an end (1998: 8), Alexander remained deeply engaged in theoretical sociology, producing what has been interpreted as a fifth volume of *Theoretical Logic* in his book, *Twenty Lectures* (1987), which examines postwar social theoretical developments and their presuppositional orientations to the problems of social action and order. Likewise, in a series of essays that examine how intellectuals have narrated, coded, and explained their epochs (modern, anti, post, and neo), Alexander's orientation to the field became increasingly metatheoretical, cultural, and more purely social theoretical. Characteristic of these works, which represent and powerfully reiterate the rationale for his postpostivist challenge to future theorizing, Alexander declares, "there is always an eschatology, not merely an epistemology, in theorizing about social change" (1995: 10; see also Alexander, 2013, for essays from this period analyzing evil, domination, and the decivilizing aspects of modernity).

Strong Program in Cultural Sociology

A second thread in Alexander's work began to take clear form in the mid-1980s and grew into programmatic maturity over the remainder of the decade. During a year at the Institute for Advanced Study near Princeton, in 1985–86, Alexander wrote drafts of two papers in the language of a strong cultural sociology: "Culture and Political Crisis: Watergate and Durkheimian Sociology" (1988a), and "The Promise of a Cultural Sociology: Technological Discourse and the Sacred and Profane Information Machine" (1993). By the turn of the century, 'cultural sociology' would be synonymous with Alexanderian sociology.

One critical ingredient in fomenting Alexander's turn to culture came through one of his earliest engagements with the German sociology scene, a practice of intellectual exchange that he has engaged in regularly throughout his career. In 1983, Alexander (1988b: xi) participated in a conference on "Emile Durkheim's Sociology of Religion" at the Werner Reimers Stiftung Foundation in Bad Homburg, Germany. The exchange spurred in Alexander (1986a,b) a thorough reinvestigation of Durkheim's intellectual trajectory from materialism to subjectivism, as well as his own turn to interdisciplinarity, through which Alexander found scholars in neighboring academic disciplines who had extended and refined the fertile terrain of symbolic classifications that Durkheim had so powerfully elaborated in his late work, *The Elementary Forms of Religious Life*. In the following years, Alexander (1988c) incorporated into his theorizing of cultural sociology Ferdinand Saussure's semiotics; elements of structuralism from the anthropology of Levi-Strauss, Mary Douglas, Marshall Sahlins, and Clifford Geertz; a model of flow from Victor Turner's work on social dramas; Roland Barthes's literary and narrative theory; Foucault's work with discourse; and his mentor Robert Bellah's development of symbolic realism.

In one of his first empirical investigations into demonstrating the purchase of this cultural framework, "The Promise of a Cultural Sociology: Technological Discourse and the Sacred and Profane Information Machine," Alexander (1993) challenges the thesis that the modern world is increasingly being dominated by a creeping technical rationality, a legacy of Weber's iron cage metaphor and Marx's assertion that all human relations will be rendered into commodity form. Using popular representations of the computer's rise and increasing ubiquity in American society, in which the technological artifact is folded into cultural frameworks of salvation and apocalypse, Alexander identifies the "omnipresent shaping of technological consciousness by discourse," and concludes that it is only through understanding this process of cultural constitution can we "gain control over technology in its material form" (192).

Likewise, in his early writings on domestic American politics, two familiar sources of motivation informing Alexander's investigations into how the cultural world shapes social life can be seen: a theoretical challenge to overcome contradictions and conflations within Parsons's approach to reconciling values and culture with social system integration, on the one hand, and

explaining and understanding Nixonian America and the Watergate scandal, on the other. Alexander wrote three versions on the topics, and over the course of these drafts, the emergence of a strong cultural sociology can be seen: Parsons dominates the first version (1984), while Durkheim's 'religious sociology,' and a dramaturgical sensibility interspersed with concepts from anthropologist Victor Turner's work on social dramas, dominate the last (1988a).

Empirically Watergate continued to prove fertile terrain as well. It was in 1985, while watching 50 hours of condensed video footage of the *CBS Evening News with Walter Cronkite*, footage selected for containing the term 'Watergate,' that Alexander first conceived of 'a noncontingent binary structure' that shapes interpretations of social and civil life in the American collective imagination (2006: 572–573, note 10). In two publications in the early 1990s Alexander pursued this idea and produced a theory of the binary codes of civil society, a framework that would critically inform much of his subsequent writings on democracy and the civil sphere. In "Citizen and Enemy as Symbolic Classification," Alexander (1992) asserts that in as much as it is an institutional realm or the province of elites' interests, civil society is also a "structured, socially established consciousness, a network of understandings that operates beneath and above explicit institutions and the self-conscious interests of elites." This consciousness, he argues, is a set of distinctive symbolic codes that define the basic categories of citizens' understandings that distinguish the pure and the impure as well as the democratic and the counterdemocratic and establish the differences between liberty and repression. This binary code, Alexander states, constitutes "the very sense of society for those who are within and without it" (290).

The theory of the binary codes of civil society elaborated in Alexander's "Citizen and Enemy as Symbolic Classification" (1992) would become programmatic. The theory is most frequently associated, however, with the argument's second – revised and empirically extended – iteration, namely, in "The Discourse of American Civil Society" (1993), which Alexander cowrote with his former graduate student and periodic coauthor, Philip Smith. In it the authors further develop Alexander's theory of the binary codes of civil society, and substantiate it with an extended empirical investigation. Examining American political crises and scandals from the 1830s through the 1980s, Alexander and Smith demonstrate that an enduring binary code, or a cultural framework of understanding, has been repeatedly invoked by antagonists in these events in their efforts to portray themselves in positive, democratic hues, and their enemies as motivated by profane, counterdemocratic tendencies. Through this investigation into conflicts throughout the history of American civil society, Alexander and Smith identify "the durability and continuity of a single culture structure over time," a structure "which is able to reproduce itself discursively in various highly contingent contexts" (1993: 198).

In an early and succinct manifesto for a cultural sociology, in an American Sociological Association (ASA) Culture section newsletter contribution titled, "Cultural Sociology or Sociology of Culture? Toward a Strong Program" (1996), Alexander draws a strict line distinguishing 'cultural sociology' from the 'sociology of culture,' and argues that the latter routinely frames culture as a dependent variable to be explained by something entirely outside the realm of meaning itself. To do cultural sociology, rather, means one must subscribe to the idea that "[e]very action, no matter how instrumental and reflexive vis-à-vis its external environments … is imbedded in a horizon of meaning (an internal environment) in relationship to which it can be neither instrumental nor reflexive" (1996: 3; see also Alexander and Smith, 2002).

Alexander designed the strong program and adumbrated its contours. In no small measure it has been his eagerness to work with graduate students over the past two decades that has helped this perspective into develop into a fully formed intellectual movement. Many of these students went on to academic careers, and representatives of the strong program in cultural sociology are found in sociology departments across the United States, Europe, and Asia. Early contributors to the program's body of literature include former members of the Culture Club at UCLA such as Elaine Chan, Laura Edles, Ronald Jacobs, Anne Kane, Agnes Ku, Eric Rambo, Andy Roth, Steve Sherwood, and Philip Smith. Contributors from more recent generations include Dominik Bartmanski, Elizabeth Breese, Shai Dromi, Rui Gao, Nadya Jaworski, Jason Mast, Lisa McCormick, Matthew Norton, Eyal Rabinovitch, and Isaac Reed. Also a testament to the movement's vitality, Alexander launched with Ronald Jacobs and Philip Smith *The American Journal of Cultural Sociology*, a peer-reviewed journal dedicated to publishing new developments in meaning-centered sociology.

The Civil Sphere and Civil Society

Alexander published his magnum opus, *The Civil Sphere*, in 2006. It is substantial in size and scope, ambitious and creative in its theorizing, and thorough and illuminating in its empirical detail. It is also the culmination of over two decades of work in democratic, social, and political theory; it is representative of his cultural sociology; and it incorporates important dimensions of his recent interventions in social performance, trauma, and iconicity. It is the thread to which the other three threads in this article all join and form the representative image of Alexander's overarching project.

Alexander received a fellowship from the John Simon Guggenheim Memorial Foundation in 1979 to pursue a project titled, "Watergate and the Crisis of Civil Society." Civil repair was a pressing concern in the wake of the Watergate crisis, and it was at this time that Alexander (1980) started pursuing an interest in social solidarity, and in-group/out-group, inclusion/exclusion processes in modern society. But it was in the mid-1980s that his grand vision of a theory of civil society began to take fuller form. In addition to turning to cultural theory during this time (discussed above), Alexander received an invitation from political philosopher Michael Walzer to spend a year (1985–86) at the Institute for Advanced Study in Princeton, New Jersey. Walzer had influenced Alexander during the latter's formative, undergraduate years, when they were both at Harvard. It was during his second meeting with Walzer at the Institute of Advanced Study (IAS) that Alexander turned more directly to engaging classical and contemporary democratic theory.

Shortly after his stay at the IAS, civil society would become a central issue not only in academic discourse but also in popular discourse. In the introduction to his edited volume, *Real*

Civil Societies (1998), Alexander recounts making his first return to Eastern Europe in 1990, following the initial phases of the Soviet Union's dissolution. He witnessed Hungary and Poland celebrating the return of civil society, and it was at this time, Alexander reports, that he experienced civil society not just as an 'ideal' but as a 'real' force in society; that civil society was, indeed, a social fact (1).

If it was during his trip to Hungary that his new theory of the civil sphere 'crystallized in its final form,' then it was over the course of the following decade that Alexander began laying the foundations for what would become *The Civil Sphere*.

For instance, in "Bringing Democracy Back In" (1991), Alexander argues that democracy is not just a formal arrangement, and politics is not just the self-interested pursuits of elites and oligarchs. While they are, in part, these things, they are also about a medium of communication and are constituted by a symbolic code (160). With the ideal of theoretical multidimensionality shaping his argument, Alexander concludes that, distinct from the state, civil society is a "realm of solidarity and cultural universalism but also … an institutionalized and differentiated social sphere" (171). Alexander then turned to exploring the paradoxes of civil society (1994), and to articulating a new theory of social movements (1996) in which he argues that they represent social devices that "construct translations between the discourse of civil society and the institution-specific process of a more particularist type." Social movements succeed, he concludes, to the extent that they are able to "employ the civil metalanguage" that will relate the movement's "practical problems to the symbolic centre of society and its utopian premises" (229). From 1998 to 2001, Alexander's theory of the civil sphere assumes its full form as he identifies the three ideal typical forms of theorizing about it (1998), argues that the contemporary world is characterized by partial and plural utopian visions that are oriented toward difference and the utopia of civil repair (2001a,b), and theorizes the three modes of incorporation, namely, assimilation, hyphenation, and multiculturalism (2001c).

The Civil Sphere appears in print in 2006 with Alexander having built on and extending this theoretical framework, incorporating his newly formed theories of social performance (2004a) and cultural trauma (2002, 2004b), and having produced in-depth analyses of empirical cases on gender and motherhood (Part III), the civil rights movement (Part III), and the American Jews (Part IV). Upon publication, *The Civil Sphere* gained enormous attention, sparked considerable debate, and won awards such as the Culture Section of the American Sociological Association's Mary Douglas Prize for Best Book (2008), and the American Publishers Award for Professional and Scholarly Excellence in Sociology and Social Work (2006).

Cultural Theories of Action and Materiality

Approaching his fourth decade as an academic, Alexander remains as productive and imaginative in his interests and writings as at any time during his career. Creating a macrodramaturgical theory of action, one that resists subsuming meaning to practice, in "Cultural Pragmatics: Social Performance Between Ritual and Strategy," Alexander (2004a) specified a conceptual framework designed for analyzing events in complex, differentiated societies. Alexander's argument offers a historical reconstruction of the development and professionalization of theater and criticism and illustrates how over time social formations have moved from fused conditions organized by rituals, to the conditions of defusion, which are organized by 'ritual-like,' performative processes (see also Alexander et al., 2006).

Demonstrating the theory's purchase, Alexander (2010) examines Barack Obama's first campaign for the presidency. Alexander argues that the challenge before those who aspire to power includes refusing the elements of performance, and performing meaningful scripts that engage the audience's understandings of national identity and democracy. Would-be leaders must 'work the binaries,' or stage performances in which they cast themselves as representative of the sacred, democratic code of civil society while casting their opponents as polluted, profane, counterdemocratic characters. They must also 'walk the boundaries' that separate the civil and uncivil spheres in contemporary American society; they must perform the delicate task of identifying themselves with more particularistic spheres like race, class, gender, religion, and ethnicity, while signaling that if they win office they are capable of containing these particularistic dimensions and assuming the more universalist persona of the ideal civil actor.

Alexander has also turned to iconicity to create a cultural theory of materiality (2008a,b; see also Alexander et al., 2011). Iconic consciousness, he states, "occurs when an aesthetically shaped materiality signifies social value" (2008: 782). Iconic experience, on the other hand, is triggered when an artist successfully shapes a surface in such a manner that it draws the viewer deeper into contact with iconic meaning. Alexander describes how in this process "the aesthetic object becomes a symbol" or collective representation, the viewer's concerns about the present or the conditions of the object's production recede, the object's specificity is replaced by a sense of "all 'such things,'" and inside the observer is stirred "a process of typification" (6). Shifting from the materiality of art to that of everyday life, Alexander asserts that people are "drawn into the experience of meaning and emotionality by surface forms," forms that "we 'feel' in our unconscious minds and associate with other ideas and things … ideas and things that are simultaneously personal and social" (6).

Abstract

An algorithm is an instruction formulated as a finite set of rules to be performed sequentially or in parallel for obtaining a solution or an approximation to the solution of a well-specified problem. It may contain subroutines that are algorithms in themselves. An algorithm can be strictly deterministic or stochastic in nature. Fundamental features of an algorithm are its complexity and its amenability to implementation.

Introduction

An algorithm can be seen as a mathematical recipe, consisting of a finite set of rules to be performed systematically that is an outcome to the solution or an approximation of the solution of a well-formulated problem. The word 'algorithm' stems from the name of the Persian mathematician Abu Ja'far Mohammed ibnMûsâ al-Khowârizm, who lived in the ninth century. Around the year 1825 al-Khowârizm wrote an influential mathematical textbook entitled *Kitab al jabrw'almuqabala*. The term 'algorithm,' or in its more original form 'algorism,' is directly derived from the last part of the author's name.

In today's scientific usage algorithms can be sequential or parallel. In sequential algorithms the steps forming the algorithm are ordered and should be performed one after the other. In parallel algorithms some of the rules are to be performed simultaneously. Algorithms can be graphically represented by flowcharts composed by arrows and boxes. The boxes contain the instructions and the arrows indicate transitions from one step to the next. Algorithms were known much earlier than the eighth century. One of the most familiar, dating from ancient Greek times (*c*.300 BC), is the procedure now referred to as Euclid's algorithm for finding the highest common factor of two numbers.

Algorithms often depend on subalgorithms that can be seen as instructions pertaining to subtasks to be tackled as parts of the process. For instance, the algorithm for obtaining the highest common factor of two numbers relies on the algorithm for finding the remainder obtained when dividing two numbers a and b. Dividing two (natural) numbers a and b, is something we learn at school after having learnt the multiplication tables by heart. Usually we perform a division by reducing it to a sequence of multiplications and subtractions. Yet assume for the moment that to perform division we cannot rely on multiplication, nor can we express numbers in base 10. Both of these operations will require additional algorithms. We represent numbers in a very primitive form by simply writing a sequence of dots. Thus •••••, for instance, represents the number 5.

The remainder algorithm works as follows (using $17 \div 5$ as an example):

(a) Write the sequence of dots for the dividend (17 in this case).
(b) Erase as many dots as correspond to the divisor (5 in this case).
(c) If the remaining number of dots is larger than or equal to the divisor go back to (a).
(d) If the remaining number of dots is smaller than the dividend print out this number.
(e) STOP.

Figure 1 represents the flow chart of the algorithm 'find the greatest common divisor' of a and b. The algorithm just described contains a loop. Observe that for any pair of numbers the algorithm produces the answer in a finite number of steps. Applied to our example of $17 \div 5$, the algorithm performs the following steps:

Current state	*Operation*
START	Write 17 dots
••••••••••••••••••	Erase 5 dots
••••••••••••	Erase 5 dots
•••••••	Erase 5 dots
••	Print 2 dots
STOP	

Figure 1 Flow chart of the algorithm 'find the greatest common divisor' of a and b.

The computational algorithm for finding the remainder of an integer when divided by another integer can be used as a subalgorithm of the decision algorithm for the problem 'Does *b* divide *a*?' (the answer is 'yes' if the remainder is zero). Repeated application of these algorithms produces the answer to the decidable question 'Is *a* a prime?' (the answer is 'no' if *a* is divisible by any smaller number besides 1).

An algorithm or a machine is deterministic if at each step there is only one possible action it can perform. A nondeterministic algorithm or machine may make random choices of its next action at some steps. An algorithm is called a decision algorithm if it leads to a 'yes' or 'no' result, whereas it is called a computational algorithm if it computes a solution to a given well-defined problem.

Despite the ancient origins of specific examples of algorithms, the precise formulation of the concept of a general algorithm dates only from the last century. The first rigorous definitions of this concept arose in the 1930s. The classical prototype algorithm is the Turing machine, defined by Alan Turing to tackle the *Entscheidungsproblem* or decision problem, posed by the German mathematician David Hilbert in 1900, at the Paris International Congress of Mathematicians. Hilbert's dream was to prove that the edifice of mathematics is a consistent set of propositions derived from a finite set of axioms, from which the truth of any well-formulated proposition can be established by a well-defined finite sequence of proof steps. The development and formalization of mathematics had led mathematicians to see it as the perfect, flawless science.

Algorithms and the *Entscheidungsproblem*

In 1931, the foundation of mathematics suffered its most crushing blow from a startling theorem proven by the Austrian logician Kurt Gödel. Gödel showed that any mathematical system powerful enough to represent arithmetic is incomplete in the sense that there exist propositions that cannot be proven true or untrue in a finite sequence of steps. Such propositions are said to be undecidable within the given system. Turing had been motivated by Gödel's work to seek an algorithmic method of determining whether any given proposition was undecidable, with the ultimate goal of removing undecidability as a concern for mathematics. Instead, he proved in his seminal paper 'On computable numbers, with an application to the *Entscheidungsproblem*'(1937) that there cannot exist any such universal method of determination.

The question of establishing whether the number of steps required for a given problem is finite or infinite is called the halting problem. Turing's description of the essential features of any general-purpose algorithm, or Turing machine, became the foundation of computer science. Today the issues of decidability and computability are central to the design of a computer program – a special type of algorithm – and are investigated in theoretical computer science.

The question whether intelligent problem solving can be described in terms of algorithms was extensively examined by Herbert Simon in the late 1940s and early 1950s. Newell and Simon proposed the first computer programs for problem-solving algorithms as well as the first programs for algorithms that prove theorems in Euclidean geometry, thus founding the new discipline of Artificial Intelligence (*see* Artificial Intelligence: Genetic Programming).

Around the same time McCulloch had developed a formal model of a neuron (McCulloch and Pitts, 1943), proving that artificial neurons are capable of performing logical operations. An artificial neuron is a device that produces an output that is a function of its inputs if the sum of the inputs exceeds a threshold and otherwise produces no output. The subdiscipline of computer science known as neural networks deals with systems of artificial neurons firing in sequence and/or in parallel, in analogy to the operation of biological neurons.

The Complexity of an Algorithm

One important feature of an algorithm is its complexity. A number of definitions of complexity have been put forward with the most common being time complexity, or the length of time it takes for an algorithm to be executed. Clearly, algorithms with low time complexity are to be preferred to ones with higher time complexity that solve the same problem. The question of establishing a formal definition of complexity was answered and treated formally in theoretical computer science (*see* Algorithmic Complexity).

One possibility is to count the number of operational steps in an algorithm, express this number as a function of the number of free parameters involved in the algorithm, and determine the order of complexity of this function. The order of complexity of a function f is denoted by O(f), where O( ) is usually called the Landau symbol, and is defined as follows: Given two functions $F(n)$ and $G(n)$ defined on the set of natural numbers, we say that F is of the order of G, and write $F = O(G)$, if there exists a constant K such that:

$$\frac{F(n)}{G(n)} < K$$

for all natural numbers n. Thus, for instance, the function $F(n) = 3n+1$ is of the order of $G(n) = n$ *with* $K = 4$. Every polynomial in n, that is, every linear combination of powers of n, is of the order of its highest power of n. Because what is being counted is the number of steps in a sequential process, which is common to view the resulting O( ) criterion as the time complexity of the algorithm, where n denotes the length of the given input.

The notion of algorithm complexity led to a fundamental classification of problems. They are classified as belonging to P or NP, where, as we shall see, this 'or' is not exclusive. P is a shorthand for 'polynomial time' and stands for the set of all problems that can be solved by a deterministic algorithm in polynomial time, which means that the number of operations required by the algorithm can be expressed in terms of a linear combination of powers of n, where n is the number of free parameters. NP is the class of all problems that can be solved by nondeterministic algorithms in polynomial time. The strength of nondeterminism lies precisely in the machine's freedom to search through a large space of possible computations by means of a nondeterministic or stochastic process. Clearly, the relation $P \subseteq NP$ holds. One of the unsolved

problems in computer science is to establish whether P = NP (Garey and Johnson, 1979). Problems for which low complexity algorithms exist (i.e., problems in class P) are called tractable; other problems are called intractable.

Monte Carlo Methods

An important category of nondeterministic algorithms is the class of Monte Carlo methods, introduced around 1940 by Metropolis, von Neumann, and Ulam. The term derives from the gambling games that are an economic mainstay of the city of that name, and originated during World War II as a code name for stochastic simulations associated with nuclear research. The most common application of Monte Carlo methods is to approximate intractable integrals. If $X_1, \ldots, X_n$ are random draws from a probability distribution with density function $f(x)$, then $S_n = \frac{1}{n}\sum_i h(X_i)$ has an expected value,

$$E[S_n] = \int_x h(x)f(x)\mathrm{d}x \qquad [1]$$

and satisfies the central limit theorem. Thus, a difficult integral can be approximated by representing it in the form (1) and executing the following nondeterministic algorithm:

(a) Simulate a random number X_n from the distribution $f(x)$.
(b) Compute the average $S_n = \frac{1}{n}\sum_{i=1}^{n} h(x_i)$.
(c) Estimate whether sufficient accuracy has been achieved.
(d) If yes, STOP; otherwise return to (a).

A common strategy for increasing accuracy in a problem that does not admit exact solutions is to decompose it into subproblems such that the exact algorithms for tractable subproblems can be combined with Monte Carlo estimates for intractable subproblems to obtain accurate approximations to the whole problem. Monte Carlo simulations are important tools in fields such as physics, statistical analysis, stochastic neural networks, and optimization.

Algorithms for Learning

Since the inception of formal algorithms, an important question has dealt with the conditions under which algorithms can be designed to learn from experience. The idea is that an algorithm that learns from experience becomes more and more adequate for solving the problem in question. The last two decades of the twentieth century witnessed an explosion of algorithms that can perform learning tasks and a sound theoretical understanding of learning machines is beginning to emerge. The theoretical and empirical study of learning algorithms is called Machine Learning. One type of learning machine is typical of neural networks that modify their weights by adapting them to feedback information on their performance. Another type of learning machine is provided by what is known as a 'genetic algorithm,' where there is a natural selection between algorithmic procedures and the most effective algorithm arises by a form of survival of the fittest.

Yet another type of learning can be materialized as a search through a large set of possible algorithms for a given problem (*see* Algorithmic Complexity). Here the type of algorithm is fixed from the beginning and what is searched for is the optimal realization of this algorithm, that is, a realization that fits the given data best. Thus learning becomes a special form of model selection. For many problems, including search across models, exact solutions are intractable yet tractable heuristics (or rules-of-thumb) work well for a large class of problem instances. As an example, consider the problem of finding an optimal decision tree algorithm to represent a given decision rule. A decision tree is a graphical representation of a rule for making a categorization decision. The graph for a decision tree consists of nodes and edges pointing from nodes (called parents) to other nodes (called children). One node, called the root node, has no parents. Each other node has exactly one parent. At the bottom of the tree are the leaf nodes, which have no children. With each nonleaf node is associated a rule which selects a child to visit depending on information passed from the parent node.

With each leaf node is associated a rule for computing a value for the node. The decision tree algorithm proceeds as follows:

(a) Begin at root node.
(b) Execute rule to decide which arc to traverse.
(c) Proceed to child at end of chosen arc.
(d) If child is a leaf node, execute rule to compute and print value associated with node and STOP.
(e) Otherwise, go to (b).

It is frequently desired to find an optimal decision tree for a given classification problem and a given criterion of optimality. There are exponentially many possible decision trees for a set of n pieces of information and thus, searching for optimal trees is often an intractable problem. Tractable heuristics have been suggested in machine learning that help find trees good enough for given problems. One such type of classification tree has been introduced by Breiman et al. (1993) and is known as CART, which is an abbreviation of classification and regression tree.

The study of algorithms has been highly influential in psychology. The behaviorist view which emphasizes the relationship between sensory inputs and motor outputs has given way to the cognitive view, which emphasizes the role of internal cognitive states in producing behavior. Information processing models of cognition have thus become a mainstay of cognitive psychology. Hypotheses about the manner in which cognition influences behavior are encoded as algorithms and implemented in a computer software that is used to simulate behavior. Simulated results are then compared to the behavior of human or animal subjects to validate or refute the hypotheses upon which they are based. One of the important issues in recent developments of cognitive psychology has been to establish how the mind deals with classifications and decisions under uncertainty.

Simple Algorithms for Classification Previous to Decision Making: Fast and Frugal Trees

While some schools in the psychology of decision making have defended the approach of classical rationality for which

the mind functions by means of full logical and probabilistic algorithms, a recent development has viewed the unaided mind as relying on very simple heuristics for inference, which are amenable to being modeled by means of algorithms. These *fast and frugal* algorithms, as proposed by Gigerenzer et al. (1999), are actually elementary, fast in construction and execution, and robust in prediction. The most useful among them are the fast and frugal classification trees (*see* Decision and Choice: Heuristics).

Decision making often requires previous classification: Possible actions are assigned to options or alternatives, which emerge as the result of classification. Patients are classified as having or not having a disease by means of cues, which may be symptoms or the result of tests; based on these classifications, decisions are made on possible actions to be taken, like surgery or intake of medicine. Two questions arise: (1) What are the properties of good cues for this type of classification that underlies decision making? (2) What are the algorithms used for this type of classification? In order to answer the first question a concrete example from medical decision making can be useful. In the case of one cue (e.g., a medical test like the mammogram), its *sensitivity* is given by the proportion of patients with the disease (e.g., breast cancer) that tests positive. This measure is important for establishing the goodness of the test but is not sufficient for making decisions on possible treatments, given that the patient is classified as having the disease. What the doctor definitely needs to know is the positive predictive value, also called the validity of the test, assessed as the proportion of patients with a positive value on it, who do have the disease. As has been demonstrated empirically (Gigerenzer and Hoffrage, 1995; Brase, 2008) *natural* representations of information foster good assessments of the predictive value of a test based on knowledge on the sensitivity and vice versa, by facilitating Bayesian reasoning. A positive mammogram, though, is not sufficient for classifying a patient as having breast cancer. It is just the first of a set of tests. Other tests, like ultrasound test and tumor markers and even ambulant biopsies, belong to the medical routine for classifying a patient as requiring global mastectomy or some alternative local treatment.

The answer to the second question is more subtle and there is a plethora of models proposed by both statistics and artificial intelligence for classification. A survey of the literature on these models for classification can be found, for instance, in Berretty et al. (1999). Bayesian classification becomes cumbersome already for three cues and is computationally intractable when several cues have to be taken into account. Even simplifications of the full Bayesian procedure based on natural frequencies become utterly complicated when several cues are considered. There exist more synthetic Bayesian procedures, such as Bayesian networks, but these are also NP-complete (Cooper, 1990).

How do people perform binary classifications based on several cues, when in hurry and when both time and information are costly? A concrete example may illustrate this situation: how do doctors establish, for instance, that a patient should or should not have surgery, based on the results of a set of tests? Or, more concretely, how do doctors classify a patient with severe chest pain as one that should be treated in the Coronary Care Unit? Two researchers of the University of Michigan P. Green and A. Mehr (Green and Mehr, 1997) investigated this question from an innovative perspective that caused a paradigm change in the theory of human classifications and decision making. This is the situation they analyzed: in a Michigan hospital, doctors used to rely on their clinical judgment in order to decide whether a patient with intense chest pain has to be assigned to the coronary unit, right away, or whether he should instead rest in a regular hospital bed for treatment. The doctors ended up sending about 90% of the patients to the coronary care unit. This 'defensive' strategy led to excessive costs, reduced the quality of care provided and introduced new risks. The two researchers from the University of Michigan were called to solve this problem.

Green and Mehr investigated the effect of an intervention, in the course of which physicians were trained to use logistic regression rather than to rely on their clinical judgment (Green and Mehr, 1997). The *Heart Disease Predictive Instrument* (Pozen et al., 1984) consisted of a chart with more than 50 probabilities and a logistic regression formula with which the physician can compute the probability that a patient has acute ischemic heart disease. If the probability is higher than a critical value, then the patient is classified as being in a high risk and sent to the coronary care unit, otherwise not. But physicians were not happy using this and similar systems. They did not understand it. It is not transparent and appears to suggest that clinical judgment should depend on a pocket calculator. The physicians seemed to be using some of the information in the charts – such as what symptoms are diagnostic and which symptoms are more diagnostic than others – but ignored the quantitative aspects of the information in terms of exact probabilities. That opened up a third alternative: the probabilities and computations of the logistic regression may not matter much at all for achieving high accuracy. Based on this observation Green and Mehr (1997) constructed a heuristic by using three building blocks: (1) ordered search, (2) fast stopping rule, and (3) one-reason decision making. The resulting classification heuristic is shown in **Figure 2**. It asks only a few yes-or-no questions and has an exit at every level. If a patient has a certain anomaly in his electrocardiogram – the so-called ST segment change – he is immediately classified as being at a high risk and is assigned to the coronary care unit. No other information is searched for. If that is not the case, a second question is asked: is the patient's primary complaint chest pain? If this is not the case, he is classified as low risk and put to a regular nursing bed. No further information is considered. If the answer is yes, a final question, namely whether any of those four remaining cues not associated with chest pain, is asked to classify the patient and decide on the appropriate treatment.

A surprising result concerning the performance of these fast and frugal trees is that these trees are overall more accurate in classifying actual heart attack patients than both the physicians' intuition and the logistic regression. The fast and frugal tree maximizes the proportion of patients correctly assigned to the coronary care (as measured by a subsequent myocardial infarction). At the same time it has a comparatively low false alarm rate.

Fast and frugal trees have been proposed for a variety of classification tasks (Martignon et al., 2008). Another interesting

Figure 2 A fast and frugal classification tree: it classifies patients with complains of heart pain into *high risk* or *low risk*.

example is, for instance, deciding whether, or not, to prescribe antibiotic treatment to young children suffering form community acquired pneumonia (Fischer et al., 2002). Fischer et al. (2002) proposed a very simple fast and frugal tree for making this decision. The tree uses at most two cues, whose values can be easily obtained. Initially, it is asked whether the child is older than 3 years. If the answer to this is 'no,' it is immediately concluded that macrolides should not be prescribed. Only if the answer to the first question is 'yes,' is it asked in the second level of the tree whether the child has had fever for more than 2 days. If the answer to the second question is 'no,' it is concluded that macrolides should not be prescribed and if the answer is 'yes,' it is concluded that macrolides should be prescribed. Interestingly, this tree can also be expressed as a rule easy to memorize and quick to apply: 'Prescribe macrolides only if the child is older than three years and the child has had fever for more than 2 days.' Additionally, the fast and frugal tree does not sacrifice accuracy. When evaluated and double-checked on real data, it is classified as 'high risk of microstreptococal pneumonia infection' for 72% of those children who actually were at high risk, while a scoring system based on logistic regression identified 75% of them.

Conclusion

Algorithms are the core element of thinking devices. The last century witnessed the birth of highly intelligent algorithms that replicate, often with great accuracy, some of the important achievements of the human mind. Yet, one of the most important discoveries concerning algorithms is that mathematics cannot be produced by an algorithmic procedure. This discovery, which was experienced as a crisis, can be viewed as liberating because it demonstrates the power of mathematics. Replicating intellectual, symbolic, and even basic common-sense activities by means of algorithms turned out to be daunting tasks, still mostly exceeding the grasp of computable representations.

The strategies that humans use for classification and decision are simple heuristics that can be modeled by means of very simple algorithms.

Abstract

Algorithmic complexity provides a mathematical formal notion of string complexity. Building on this, one arrives at mathematical 'gold standard' (though incomputable) definitions of randomness, induction, similarity, and even intelligence. These definitions can be turned into practical algorithms by using common compressors to approximate the universal solutions. One can consider the theories as idealized cognition with respect to which one can aim to describe actual biological cognition by listing biases and limitations that need to be defined relative to some normative reference.

Introduction

Our world contains ubiquitous examples of phenomena relying on compact representations. Some examples are the genome (Krakauer, 2002), human cognition (Chater, 1996, 1999; Chater and Vitányi, 2003), and natural languages (Zipf, 1949; Piantadosi et al., 2011) which all involve efficient use of resources. They all involve a compact code and a method of translating the code into a result. The field of algorithmic complexity (Solomonoff, 1964; Kolmogorov, 1965; Chaitin, 1969), sometimes called Kolmogorov complexity (Li and Vitányi, 2008) or Algorithmic Information Theory (Hutter, 2007a), provides a mathematical theory for such phenomena and also answers some fundamental theoretical questions about randomness (Martin-Löf, 1966) as well as telling us how to ideally make predictions about the future (Solomonoff, 1964; Hutter, 2007b; Rathmanner and Hutter, 2011). The translation mechanism mentioned above is called the reference machine and is formalized as a universal Turing machine (UTM) (Turing, 1936). The codes are programs for this machine in the form of a binary string. The result is an output of another binary string. The length of the shortest program that leads to a certain output string is called the Kolmogorov complexity of this string and can be interpreted as a measure of information content as well as of simplicity. A string with lower Kolmogorov complexity than another is considered simpler with respect to the used reference machine since it can be described more succinctly. If a string can be represented in a substantially shorter form than its naive representation, it is called compressible, otherwise incompressible. Incompressible strings look random and incompressibility is now the established definition for what it means for an individual sequence to be random. Furthermore, algorithmic complexity provides a way of defining a priori probabilities (Solomonoff, 1964) for different strings, where simpler strings are deemed more likely. From these a priori probabilities, one can derive conditional probabilities for the future as observations are made. These predictions will converge toward the true probabilities under mild assumptions on the generating process (Solomonoff, 1978; Hutter, 2007b). The assigned probabilities depend on the choice of reference machine since the Kolmogorov complexity differs by up to an additive constant for any pair of machines. This constant can make a big difference initially while the effect vanishes asymptotically. Algorithmic probability has also been combined with reinforcement learning and sequential decision theory to define an intelligent agent denoted AIXI, thereby introducing the field of universal artificial intelligence (Hutter, 2005). The agent follows a policy that maximizes expected utility with respect to the algorithmic probabilities and the utilities are defined as a sum of discounted rewards.

Algorithmic complexity has the drawback of being incomputable, though successful algorithms have been devised using practical compressors to compute crude approximations of the true complexity (Li et al., 2004; Cilibrasi and Vitányi, 2005; Veness et al., 2011). We will mention these as we outline the basic theory in the next section and then we discuss the possibility of using algorithmic complexity to provide an idealized theory of cognition. It has been argued that this model of learning resolves the 'poverty of stimulus' problem with human language acquisition (Solomonoff, 1964; Perfors et al., 2006; Hsu et al., 2013). The article ends with a Section Summary.

Basic Definitions and Results

In this section, we present the formal definitions and basic results in algorithmic complexity, algorithmic randomness, algorithmic probability, and universal artificial intelligence. We refer to Hutter (2005) and Li and Vitányi (2008) for comprehensive studies.

Algorithmic Complexity

Given a Universal Turing Machine (UTM) U, we define the Kolmogorov complexity $K(x)$ of a string x to be the length of the shortest program that makes U output x. Formally

$$K(x) := \min\{\ell(p) : U(p) = x\}$$

where $\ell(p)$ is the length of p and $U(p) = x$ means that U outputs x when given program p on the input tape. That U outputs x can be given several precise meanings. For example, it can mean that x is printed on the output tape and then the machine halts or that x is first printed and then the machine continues. K is defined by demanding that U halts after x is printed but the other mentioned variant as well as several others differs from K by at most $O(\log K)$. We here state all properties (equalities and inequalities) only up to such

a logarithmic term and they, therefore, are true for a whole range of variations on K.

We also define the conditional complexity $K(x|y)$ which is the length of the shortest program to output x given y as side information. For example, if y is a string that only differs from x by missing the last bit, then the program only has to add that bit and such a program is very short even if x is a long complex string by itself. $K(x|y)$ tells us how much information there is in x that is not in y. Furthermore, we define the joint complexity $K(x, y)$ as the length of the shortest program to output first x and then y. This can be much shorter than the sum of the shortest programs to output the individual strings since they can have much in common. It can, however, not be much longer than the sum of those since one can always create a program that first runs p_1 that outputs x and then runs p_2 that outputs y. The extra length is the length of the extra code needed for the command to first run one program and then another and is at most a constant that does not depend on x, y, p_1, or p_2. A profound result that connects all the mentioned concepts is

$$K(x,y) = K(x) + K(y|x) = K(y) + K(x|y)$$

where $=$ should, as everywhere in this article, be interpreted as being up to a logarithm and not as exact equality. This result can be rewritten as a property that is called 'symmetry of information,' stating that

$$K(x) - K(x|y) = K(y) - K(y|x)$$

This relation informally means that the amount of information y has about x ($K(x)-K(x|y)$) is the same as what x has about y. The involved quantity provides one measure of how similar they are but it is not formally a distance. However, one can transform it to

$$d(x,y) := 1 - \frac{K(x) - K(x|y)}{K(x,y)}$$

which satisfies the distance measure properties and still says that two strings are similar if they have a large amount of mutual information. Another alternative to defining a distance is $D(x, y)$ which is the length of the shortest program that converts x to y and y to x. It can be proven (Bennett et al., 1998; Mahmud, 2009) that within a constant term

$$D(x,y) := \max\{K(x|y), K(y|x)\}$$

which means that it is about as hard converting both ways as the hardest of the two directions. Both d and D are universal distance functions in the sense that if two strings are close for any computable distance function (satisfying some mild properties) then they are also close as measured by d or D. In other words, d and D pick up any possible computable regularity between any two given strings.

A normalized version of D called the normalized compression distance

$$\tilde{D}(x,y) := \frac{\max\{K(x|y), K(y|x)\}}{\max\{K(x), K(y)\}}$$

was introduced by (Li et al., 2004) where it was also proven to be universal. Furthermore, Li et al. (2004) introduced practical approximations using common compressors, namely they defined the normalized compression distance by

$$\mathrm{NCD}(x,y) := \frac{Z(xy) - \min\{Z(x), Z(y)\}}{\max\{Z(x), Z(y)\}}$$

where $Z(x)$ is the size of the compression of x. By using NCD as a similarity measure, Li et al. (2004) inferred an evolutionary tree from DNA sequences as well as the language tree from the text of the UN declaration of human rights in 52 languages. Other applications include clustering of music as well as finding the phylogenetic tree of chain letters (Bennett et al., 2013; Cilibrasi and Vitányi, 2005). This method of clustering is sometimes referred to as algorithmic clustering or clustering by compression.

Algorithmic Randomness

It is clear that $K(x) \leq \ell(x)$, where $\leq$ is up to a logarithm as always (though here true for a constant) and $\ell(x)$ is the length of the string, since one can write a program that says Print(x). The extra constant length is the Print command. If there is no shorter program than this, i.e., $K(x) \geq \ell(x)$ we say that x is incompressible and random. The notion of randomness based on incompressibility is also called Martin-Löf randomness (Martin-Löf, 1966) and has been found to be similar to human perception of randomness (Griffiths and Tenenbaum, 2003). Intuitively something is random if no regularities can be found in the string.

Algorithmic Probability

Based on a chosen reference machine U, the algorithmic a priori probability of a string x is

$$M(x) := \sum_{p:U(p)=x} 2^{-l(p)}$$

which can be interpreted as the probability that the string x is the output from U if zeros and ones are placed by independent balanced coin flips on the input tape. The sum of terms $2^{-l(p)}$ for all programs p (in a prefix free set of programs) is upper bounded by 1, according to Kraft's inequality. They do not sum to exactly one and M is actually just a semimeasure though it can be renormalized to a proper probability measure. Given any string x, one would then say that the probability of the next bit being a one is

$$M(1|x) := \frac{M(x_1)}{M(x_0) + M(x_1)}$$

$M(x)$ is closely approximated by $2^{-K(x)}$. This is because much of the mass of $M(x)$ comes from the shortest program. Furthermore, one can prove (Li and Vitányi, 2008) that if one samples a string from M, one will with high probability get a string of low complexity. This is in accordance with the principle of favoring simplicity, which is often called Occam's razor. Algorithmic complexity and algorithmic probability provide a mathematical formalization of this principle.

Sequence Prediction

Ray Solomonoff developed a theory of sequence prediction using M, including his 'Prediction Error Theorem' (Solomonoff, 1978) stating that

$$\sum_{x\in\{0,1\}^*} \mu(x)(M(0|x)-\mu(0|x))^2 \le K(\mu)\frac{\ln(2)}{2},$$

for any computable measure μ. This implies, by rewriting the left-hand-side as $\sum_{j=0}^{\infty}\sum_{\ell(x)=j}\mu(x)(M(0|x)-\mu(0|x))^2$, that with μ-probability 1

$$M(x_n|x_1x_2\ldots x_{n-1})\to\mu(x_n|x_1x_2\ldots x_{n-1})$$

as $n\to\infty$ and that using M we can learn any computable measure. How long it takes depends on the complexity of the true measure.

Induction

If one is interested in finding the explanation for the data and not only about predicting the future one needs to choose a program. The measure M can be understood as a mixture of all computable sequences by choosing prior probability $\Pr(p)=2^{-l(p)}$ for the program p generating the sequence. The minimum message length (Wallace and Boulton, 1968) (or minimum description length (Rissanen, 1978)) approach chooses the program

$$p^* := \operatorname{argmin}\{\ell(p) : U(p) = x\}$$

This is the least complex hypothesis that fits the observed data. The choice can also be understood as maximizing the posterior probability $\Pr(p|d)=\Pr(d|p)\Pr(p)/\Pr(d)$. This latter expression also extends to having a prior over classes of stochastic hypothesis where a trade-off between how well data fit the hypothesis (i.e., $\log\Pr(d|\nu)$) and the prior probability $\log\Pr(\nu)$ (that can be based on algorithmic complexity (Hutter, 2005; Li and Vitányi, 2008)) is made by choosing

$$\nu^* := \arg_\nu\min\{-(\log\Pr(d|\nu)+\log\Pr(\nu))\}$$

Intelligent Agents

In this section, we consider an agent (Russell and Norvig, 2010; Hutter, 2005) that interacts with an environment through performing actions a_t from a finite set $\mathscr{A}$ and receives observations o_t from a finite set $\mathscr{O}$ and rewards r_t from a finite set $\mathscr{R}\subset[0,1]$. Let $\mathscr{H}=(\mathscr{A}\times\mathscr{O}\times\mathscr{R})^*$ be the set of histories. A function $\nu:\mathscr{H}\times\mathscr{A}\to\mathscr{O}\times\mathscr{R}$ is called a deterministic environment. It is called a stochastic environment if instead the resulting (o, r) is stochastic. A function $\pi:\mathscr{H}\to\mathscr{A}$ is called a (deterministic) policy or an agent. The value function V is defined based on geometric discounting by $V_\nu^\pi(h_{t-1})=\sum_{i=t}^{\infty}\gamma^{i-t}r_i$ where the sequence r_i are the rewards achieved by following π from time step t onward in the environment ν after having seen $h_{t-1}\in\mathscr{H}$. If the environment is stochastic we define V using an expectation.

Given a countable class of environments $\mathscr{M}$ and strictly positive prior weights w_ν for all $\nu\in\mathscr{M}$, the a priori environment ξ is defined by letting $\xi(\cdot)=\sum w_\nu\nu(\cdot)$ and a rational agent (Hutter, 2005) is defined by following the policy

$$\pi^* := \arg_\pi\max V_\xi^\pi(\varepsilon)$$

where ε is the empty initial history. In particular the AIXI agent (Hutter, 2005) is based on the same construction of a Solomonoff prior M as in the sequence prediction case. Though the agent is incomputable, practical approximations exist, e.g., MC-AIXI-CTW (Veness et al., 2011).

Cognition and Algorithmic Complexity

Human cognition is naturally very complex as it is an artifact of evolution. However, it is still meaningful to try to identify some of the fundamental principles that are involved with some consistency. After all, cognition operates with limited resources and has evolved to support survival. Cognitive science has discovered many systematic biases (Kahneman et al., 1982) but a question is biases from what ideal. The ideal is usually assumed to be rationality (Chater and Oaksford, 1999; Tenenbaum et al., 2011) in the decision theoretic sense of the word, i.e., expected utility maximization with respect to some of the priori probabilities. Another general principle is a preference for simplicity (Chater, 1996, 1999; Chater and Vitányi, 2003). Starting with rationality and a preference for simplicity, algorithmic complexity, as we have described in Section Basic Definitions and Results, provides a formal 'gold standard' theory for sequence prediction, choosing hypotheses, judging similarity, deciding what is random and acting rationally.

Language Acquisition

Noah Chomsky has famously argued (Chomsky, 2005) that the 'poverty of stimulus' makes the language learning observed in children impossible without an innate grammar. The argument is centered around the lack of negative examples. It has been argued that a rational simplicity-biased approach, formalized using information theory, can in fact perform this task (Solomonoff, 1964; Perfors et al., 2006; Hsu et al., 2013). This simplicity bias is replacing the need for an innate grammar but can possibly be viewed as a soft version of the same, i.e., a preference for certain syntax, based on what is judged to be simple given the reference machine.

Sequential Decision Making

The AIXI agent (Hutter, 2005) is formalizing the same combination of simplicity and rationality as in the sequence prediction setting for the sequential decision-making setting. The sequential decision setting, where you make a sequence of decisions that does affect the environment, is far more complicated than performing inference from gathered data. In the sequential setting you are gathering data as you act in the environment and to gather useful data is important as well as achieving high immediate rewards. The data you gather at one time point allows you to make better decisions later on and receive more reward then. This is known as the exploration-exploitation dilemma. A common method to deal with this when building reinforcement learning agents is to introduce optimism into the agent (Szita and Lörincz, 2008; Sunehag and Hutter, 2012a). Optimism is also a principle that applies broadly in human decision making (Weinstein, 1980) and a case can be made that it should be considered another

fundamental principle rather than a bias to overcome. The AIXI agent can be modified (Sunehag and Hutter, 2012b) to incorporate optimism in a manner consistent with multiple-prior expected utility (Gilboa and Schmeidler, 1989), though reversing pessimism to optimism. These agents have better guarantees for asymptotic optimality, consistent with the empirical observation that the practical MC-AIXI-CTW agent needs more exploration heuristically added for good performance.

Two other issues are the choice of discount function and the choice of reference machine. In this article we describe AIXI based on geometric discounting while the fully general formulation can be found in Hutter (2005). Humans often display a more hyperbolic than geometric discount scheme (Laibson, 1997). The geometric discount is often considered preferable because it is time consistent (Lattimore and Hutter, 2014).

Finally, it has been discussed (Li and Vitányi, 2008) what a natural choice of reference machine would be. The choice will matter as long as we are considering a limited amount of data while asymptotically it does not. An agent based on cellular automata might have a very different sense of what is simple than a human does. The concept of a natural Turing machine could be interpreted as a reference machine that provides a notion of simplicity that agrees with human judgment. The computer programming languages that we create to make it easier for us to program computers capture to some extent a human notion of simplicity. The attempts at finding a more objective notion of a natural Turing machine have so far failed and such a choice might not exist (Müller, 2010). A recent alternative suggested by Sunehag and Hutter (2014) is to learn a reference machine for which Occam's razor is true as a proposition about the relevant world.

Defining and Measuring Intelligence

Given a reference machine and the corresponding universal mixture environment ξ, the quantity V_ξ^π has been considered as a universal intelligence measure (Legg and Hutter, 2007). It has much in common with more narrow standard human IQ tests where a person's task is to see patterns in, e.g., a sequence of numbers and guess their continuation. In principle, one can argue for any next number and find intricate mathematical patterns motivating very different answers. What makes the answers well defined is that there is an implicit simplicity bias. The continuation should be based on the simplest pattern. If one can find the simplest program explaining what has so far been observed from an unknown environment and take actions as if that is the true environment, one receives high reward in expectation and hence, a high intelligence score when measured by V_ξ^π. This universal measure can be seen as a more complex generalization of human IQ tests which have actually been successfully attacked by machine intelligence (Sanghi and Dowe, 2003). This achievement has lead to the conclusion that current IQ tests are too narrow to measure general machine intelligence which can be tailored to the task (Dowe and Hernndez-Orallo, 2012). An approximation to the universal test has recently been introduced (Legg and Veness, 2011) and applied to test a number of agents and even more recently a large class of challenging environments has been created using Atari games (Bellemare et al., 2013).

Summary

Algorithmic complexity provides a formalization of the notions of simplicity and complexity. It leads up to a formal universal theory of sequence prediction, induction, similarity, and randomness based on simplicity-biased rationality, principles suggested as idealized human cognition. Further, for the more difficult sequential decision-making setting algorithmic complexity can again together with rationality be used to define a universal intelligent agent as well as a universal measure and definition of intelligence. For the sequential decision-making setting, there are indications that further principles like optimism should be considered fundamental and not unwanted biases. Practical approximations of the otherwise incomputable theories discussed have been built based on common compression algorithms and have been successfully used for a range of practical applications including clustering of sequence data like DNA, text, and music. Further, algorithmic complexity has also simplified proofs in mathematics and resolved philosophical problems including 'problems of induction' in the philosophy of science and the problem with 'Maxwell's demon' in statistical mechanics.

Abstract

The concept of alienation has a long and complex history as it has been used in Judeo–Christian theology, Roman law, medieval concepts of insanity, German Idealism especially in Hegel, in the dialectical materialism of Marx, and more recently, in Frankfurt School Critical Theory and in existentialism. As adopted and adapted to different disciplines, alienation serves to convey an understanding of voluntary and involuntary withdrawal from the full realization of capabilities. Thus, alienation bears a variety of meanings, ranging from its usage as a term for the general malaise of the human condition to its usage as a detailed description of the specifics of oppression through mechanisms of wage labor. In structuralist theories, alienation is understood as an inevitable outcome of the social order whether or not individuals are aware of their situation. With this assumption, researchers collect data in the widest possible economic, political, and cultural frameworks. In analyses that focus on psychological evidence, it is often assumed that people's feelings are indicators of levels of alienation. Following this assumption, research is usually based on formal questionnaires the scores of which correlate positively or negatively with broad social orientations. Recent social science researches which center, among others, on social exclusion, inegalitarianism, racism, and intersectionality refine the meanings of the term by making aspects of alienation explicit according to context. Although 'alienation' has often been contested because of its adaptability to different applications, the legacy of its many rich meanings endures. Theoretical explorations of alienation continue to demonstrate its explanatory power in relation to modernity, as disclosed in its consequences and in the procedures of its discontents from social withdrawal to social mobilizations.

When we chronicle uses of the term 'alienation' we find a set of descriptions of the human condition which are not necessarily congruent, and the mix is likely to be bewildering. In some writings, alienation is defined as identical to the oppressive aspects of human life. In others, the term points to explorations of a higher good. And in the writings of still others, the same term is deployed to describe a type of interaction which may have either implication. Each description has different consequences for the design of research and different implications for intervening in social processes. Because of the diversity, alienation has often been denounced for its inappropriate 'flexibility' and plurality of meanings. Still, the construct repeatedly emerges with renewed vigor from the ashes of fiery criticism. Its usefulness has been highlighted in diverse disciplines, among them law, theology, and medicine; it has also played an important role in philosophical, sociological, and social psychological analyses. In this article, we present a more or less chronological reading of the history of alienation, its meanings, and its uses in research, thus underlining the multiple ways in which it has figured in Western thought.

The root of the term alienation is the Latin adjective for 'other' – alienus, -a, -um. In Ancient Rome, the noun 'alienatio' was primarily a legal term related to handing over property (Buckland, 2007/1921: 228f.). In Christian theology, alienation has referred to several ways of 'othering'; most important is the perception that alienation from the Divinity is irremediable because of the primordial sin: eating the fruit of the Tree of Knowledge of Good and Evil. In more recent times, the term alienation has referred to deviation from correct doctrine (Ladner, 1983: 969). Among some theologians alienation has also been adopted as the term that describes the sinful writing of 'fiction,' that is to say, all types of writing which justify the existence of worlds other than that created by the Deity (Haidu, 1977).

Alienation, with mixed implications, has been important in different schools of philosophy. In the integrated philosophical system that Georg Wilhelm Friedrich Hegel (2007 [1770–1831]) developed, alienation figures in two different ways. As *Entfremdung*, alienation is recognized as holding a negative meaning, the process of becoming and remaining isolated, i.e., a stranger. But Hegel also recognized alienation as the positive phenomenon of externalization (*Entäusserung*). As the externalized consciousness of individuals, alienation is necessary because it turns into a collective spirit which enables the construction of *a shared culture in civil society* (Ice, n.d., www.ilovephilosophy.com). In the existentialist philosophy that evolved in the nineteenth and twentieth centuries, alienation was a central concern. For Sören Kierkegaard (1813–55), the average person, living a life of banal conformity, is alienated from his/her self-realization and transcendence. Later, Martin Heidegger (1889–1976) describes *Mann* who embraces an inauthentic life of conformity and conventionality, because he is alienated from his contingency (throwedness) and his finitude (being unto death). Later, Jean-Paul Sartre (1956), building on Hegel, shows that alienation, which is universal and inevitable, appears as a condition that may be both positive and negative. In his explication, alienation involves recognition that everyone has to get along with an 'alien Me,' i.e., with the understanding that part of one's existence is beyond subjective experience. But according to Sartre, this objectification of self and others ultimately reveals a fundamental truth, and thus alienation is not negative. As philosopher and theologian, Tillich (1886–1965) sought correlates between theology's concern with the nature of human life and the concerns of existential philosophy. He describes the 'tragic universality' of 'Entfremdung' as a negation of humanity. The isolation that he describes is a state of alienation that suffers

from a sense of unbelief (rather than faith), a desire for concupiscence (not love), and a drive for *hubris* and self-elevation rather than surrender to the omnipotent immortal (Williamson and Cullingford, 1997).

In social philosophy as well, alienation has served to indicate both positive and negative aspects of human existence. Jean-Jacques Rousseau (1712–78), for example, defined alienation as people's *voluntary* renunciation of power for the greater good of the collective. In this view, alienation is a necessary foundation of democratic social life. By contrast, Adam Smith (1723–90) described alienated individuals as those doomed to primitive surroundings whether in farming or in urban factories and thus cut off from modern culture. In theories that developed from the nineteenth to the twenty-first century, the negative implications of alienation have been beyond doubt. In philosophical anthropology, alienation is described as a social condition that thwarts human possibilities for community and the self-realization that can enable a fulfilling life (Schacht, 1992). Debates center on whether these limitations are due to capitalism, modernity, or the human condition. Major critiques of the meanings of alienation, explanations of its causes, and strategies of amelioration have had an enduring impact (see, for example, Israel, 1971; Mészáros, 1970).

Echoes of the approach of social philosophy are to be found in attempts to describe medical practices in terms of the social context. Denoting mental illness as alienation, physicians diagnosed pathological deviations from normal behavior as contingent on the social context (Jacob and Beveridge, 1995). During the century of the revolutions in France (1789, 1830, 1848, and 1871), 'alienists' attributed what was seen as a rising rate of mental illness to the excess of passion in the state of France. This perception had practical consequences in conclusions that the 'alienated' have to be treated in separate institutions, rather than in general hospitals, as had been the practice till then.

Interestingly, in literature, alienation has been hailed as both technique and topic. Thus nineteenth-century poets such as Charles Baudelaire (1821–67) and Arthur Rimbaud (1854–91) talked to the alienated condition of humankind as did Louis-Ferdinand Celine (1894–1961) in his novels in the twentieth century. From a somewhat different standpoint, writers who committed themselves to the 'new novel' in twentieth-century France sought ways of describing alienation as it unfolds in banal nonevents. Taking up a position of distance from human feeling, they saw writing as a kind of service to the possibilities embedded in the French language. Thus, at a distance, in alienation, they elaborated detailed descriptions of the surround of events rather than the events themselves (Marguerite Duras (1914–96), Alain Robbe-Grillet (1922–2008), Nathalie Sarraute (1900–99)). In research into literature, alienation is frequently found to be a fruitful entry point into the style and goals of authors.

In drama, alienation has been especially important. Sartre depicted poignant situations of alienation in didactic dramas that demonstrated implications of existentialist philosophy for action. Bertolt Brecht (1898–1956) not only wrote about the alienated condition of modern humanity under capitalism, but famously insisted that for his political dramas he wanted the audience to experience *Verfremdung* (usually translated as 'alienation'). He meant for spectators to remain at a distance from what was happening on the stage. Since such an audience can pay rational attention to how the situations are constructed, they are likely to be free to think about the political implications of the drama. Thus, in the theater, alienation is considered the foundation for generating desirable social action.

Alienation in the Social Sciences

All the meanings of alienation noted above appear at some point in the social sciences.

Like Adam Smith, Harriet Martineau (1802–76) decried the exploitation of workers which prevents them from enjoying satisfactions that accrue from work. This is especially true of women whose domestic work is a kind of total enslavement.

Describing the alienating effects of the division of labor in industrial society, Karl Marx (1818–83) moved the Hegelian dialectic from the realm of ideas to its material foundations in political economy (Marx [1844] 1977). Thus, he formalized, contextualized, and refined the meaning of alienation. In his theory, capitalist relations of production turned men into extensions of machines, estranged workers from their selves, cut them off from community support, and from the ability to control their lives effectively. In this context, alienation was a kind of summary of a complex chain of injustices. With land scarce, workers migrated to cities where they sold their labor power to factory owners who determined what to produce and how. Workers have to sell their labor and as with all commodities, the value of labor is in constant flux. Marx developed an extensive critique of capitalist political economy on the basis of his dialectical concept of alienation as the process of oppression most significantly, and the term for the outcomes, acute distress primarily economic but also psychological (Marx and Engels, 1867; Williamson and Cullingford, 1997).

Although alienation is not a term they used, Max Weber (1864–1920) and Emile Durkheim (1858–1917) also wrote about forms of alienation when they noted the adverse consequences of working conditions in modern society. For Weber (1958), alienation is concretized in rationality, the dominant value of modernity. Rational principles of calculability are applied to every domain of modern life including the work of all the 'free professions'; it shapes production and bureaucratic administration in industry as well as in politics. Calculation structures human relations and infiltrates subjectivity, incorporating every aspect of personality within an alien, and alienating system which dehumanizes people and imprisons them in 'iron cages.'

In his writings, Durkheim (1984/1893) describes both negative and positive aspects of alienation. On the one hand, he saw rationality in the 'organic' division of labor that makes industrialization possible as a basis for renewing social solidarity. On the other hand, the manifold varieties of unforeseen situations, the dynamics of industrial change, could lead to a weakening of social ties and a fragmentation of consciousness. The failure of normativity, difficulty in deciding how to apply familiar rules and how to find what new rules of behavior to adopt signals a specific condition of alienation, which was, for Durkheim, 'anomie' (1997/1897).

Conceptualizing Alienation in Critical Sociology

Basing their initial ideas on the Marxian arguments against capitalism, researchers of the school of critical sociology developed more shaded meanings of alienation (Horkheimer and Adorno, 1972). Gyorgy Lukacs (1923) explored the impact of the rational division of labor on consciousness. He described alienation as reification – a misguided perception of social relationships as concrete 'things' in a steady state. Moreover, through the embedding of reification in ideology, a distorted understanding of the social system is ensured. Because people lack a 'dialectical conception of the totality of social relations within the historical process' (Twining, 1980: 419), they remain unaware of the contradictions in the capitalist system which enforce alienation.

Members of the Frankfurt School, who relied on Lukacs' analyses of alienation for a cultural reading of Marx, and on Marx's 1844 *Manuscripts* (unknown until the 1920s), expanded on the understanding of reification (distorted readings of reality) as a means of domination. For Herbert Marcuse (1969), alienation could be positive as the ground for a total revolution. But this was only likely to emerge among those outside the systems of production, e.g., students, artists and writers, the long-term unemployed, and ethnic minorities. In the meantime, conditions of alienated labor keep people deceived, distracted, and powerless either to understand their lives or to mobilize for progressive change. Even the apparent liberation of erotic desire in late capitalism alienates persons from their 'real needs' in order to incorporate them into the 'administered society' (Marcuse, 1969). Archibald (2009) shows alienation in a different light when he reasons that workers no longer care enough about work to feel deprived by its alienating effects. Instead they channel their aspirations to consumption and leisure. Still, with consumption commercialized, mass produced, and less subject to individuals' control, aspirations can easily be frustrated. Thus, alienation imposes itself in a different way.

Additional Conceptualizations of Alienation

In various guises, the topic of alienation appears in the work of most sociologists in the twentieth century. Early in the century, alienation can be recognized in Georg Simmel's stranger who, coming from one location and staying, sometimes for a lifetime, in another, will never fully belong. Paradoxically, as an outsider who suffers from remaining a stranger, he often makes positive contributions to the collective in the new location (see Simmel in Wolff, 1950). Robert E. Park (1928: 893) extended Simmel's insight specifically to a view of the advantages of migration and its effects in creating 'marginal men' whose alienation is a positive factor for the 'new' society. While acknowledging the 'moral turmoil,' the anomie that Durkheim identified as the root of discontent, Park sees the marginality that is consequent on mobility – social or geographical – as a key to advancement and growth.

In discussing 'anomia,' Robert K. Merton (1938) presented a model of how alienation is implemented in continuities and discontinuities between culturally approved goals and institutionally available means. His typology of 'modes of adaptation' shows the outcomes of acceptance or rejection of approved goals and means. In functioning societies, most people adjust to culturally approved goals (values) by accepting institutionalized means (norms) for attaining them. This is a pattern where culturally approved goals are taken for granted and institutionally available means are adopted. Other combinations are deviant: Accepting culturally approved goals while rejecting normatively available means leads to 'innovation,' which may be beneficial for society, but this pattern may also describe role adjustments such as resorting to criminal behavior. Adherence to legitimate means when one no longer accepts culturally approved goals is alienation as a type of 'ritualism.' Rejection of both goals and means were seen as 'retreatism,' cutting oneself off from the social milieu.

A recent compilation of writing on alienation (Langman and Kalekin-Fishman, 2005) follows the Frankfurt School view that alienation is inevitable under capitalist production and that the class system shapes every domain of social life. In that volume, theoretical contributions by Harry F. Dahms, Matthew David, Lauren Langman, and David Norman Smith detail how structures of late capitalist society insinuate themselves into the realms of culture causing (mis)understandings of the world and of one's self. In the family, too, people are implicated in the capitalist mode of production as consumers (Mészáros, 1970).

A different kind of definition of meaning was proposed in Melvin Seeman's (1959) landmark literature review which departs from concerns of viewing the inevitable albeit unwitting effects of social arrangements on consciousness and on behavior. Drawing upon the ideas of Marx, Mannheim, Weber, and Durkheim, Seeman highlights five different social psychological consequences of alienation: *powerlessness*, the feeling that one is incapable of dealing with problems that arise; *meaninglessness*, the feeling that one cannot know the outcome of one's actions; *social isolation*, the feeling of not being a part of any social group; *self-estrangement*, the lack of an inability to identify where one's true interests lie. In this set, he identifies anomie, *normlessness*, the state of bewilderment about what norms are applicable in unforeseen situations, as a particular type of alienation. Later, he added a dimension that he felt was distinct, *cultural alienation*.

By the middle of the twentieth century, then, theoreticians proposed several mutually exclusive types of definition for alienation. Embedded in differently structured theoretical approaches, the various definitions play an important role in different kinds of research. In a sense, one may say that in its adaptability to different kinds of research lies the secret of the vitality of alienation as a construct in the social sciences.

Alienation Research: Approaches and Objects of Investigation

Research based on a structural view of alienation is primarily conducted holistically and contextualized historically. Although researchers of this School often look at what people say and how people act, the importance of statements and actions is taken to be derived from macrosocial trends (Braverman, 1974). As noted above, it is taken for granted that the conditions which cause alienation are likely to be well-hidden from people's consciousness and that research has the extrascientific task of shaping awareness to the point of provoking action. Thus, in this type of research there is a focus on describing the relations of production in the macro, in order

to draw conclusions about likely consequences for the conditions that people have to confront. Among studies which examine the immediate social context of more intimate situations are researches on work and organizational behavior, education, everyday life as well as gender, community, and ethnic relations. In the latter part of the twentieth century, theories of alienation were applied increasingly to studying responses to the mass media and consumerism. In sum, structural approaches to alienation research are realized at the macro-, the micro-, and the mesosocial levels.

At the same time, however, in the mid-twentieth century, in the wake of Seeman's (1959) survey of the literature, researchers showed increasing interest in the assumption that alienation can be described in full by people who suffer from it. Researchers could thus use closed questionnaires to measure the frequency and intensity of experiencing relevant dimensions of alienation. In them, respondents are asked to report on their feelings of alienation at work, in the family, among friends, and even in relation to their 'selves.' For several decades (beginning in the 1950s), many efforts were made by American researchers to produce reliable and valid scales of alienation. The objects of investigation were equally abstract as they attempted to track correlations of alienation with constructs such as liberalism, tolerance, acceptance of democracy, and life satisfaction among different groups. Gwynn Nettler's (1957) 'measure of alienation' tested the degree to which people felt alienated from their own society and its culture. Leo Srole (1956) elaborated a measure of 'powerlessness' and examined its correlation with a readiness to countenance messages about interethnic tolerance. After reducing the five dimensions delineated by Seeman (1959) to three, social isolation, powerlessness, and meaninglessness, Dwight G. Dean (1961) constructed several scales to measure alienation. He proposed that alienation could be identified in social apathy, authoritarianism, conformity, cynicism, hoboism, political apathy, political hyperactivity, personalization in politics, prejudice, privatization, psychosis, regression, and suicide. In work that assessed correlations of vegetativeness (apathy), nihilism, and adventurousness with powerlessness, significant correlations were found among all subscales (Maddi et al., 1979). This approach has not exhausted all the possibilities. Taking still a different view Davids (1955) examined alienation as related to egocentricity, distrust, pessimism, anxiety, and resentment.

The now canonic study by Blauner (1964) is a vivid example of how questionnaires could be shaped to deal with research on the structural grounds for alienation and on feelings of alienation. By circulating questionnaires to workers in four industries each of which demanded a different level of skill from employees, Blauner expected to find negative correlations between levels of skill and levels of perceived alienation. Findings confirmed his hypothesis that the lower the level of skill required for any given job, the higher the score for alienation. But Blauner also examined structural aspects of the workers' lives and ultimately could show that workers' feelings of alienation were mitigated by community solidarity.

During the youth rebellion of the 1960s, Kenneth Keniston (1971) calculated an 'alienation syndrome' that could be explained by socialization in families with a leftist orientation and by an innate 'protest-prone personality.' Scales measuring alienation are currently important in research on childhood, on maladjustment, on depression and mental illness, as well as in organizational research, in research on race and class, and in educational research of different kinds. Not all the research in this vein is of the same kind. Although almost all the scales that measure alienation were compiled in the USA, they are often adapted to research that is conducted in Africa and Asia as well as in Europe.

To this day, there are numerous researches into evidence of different dimensions of felt alienation in hospitals and prisons, as well as in political juggling and in the labor market. Much of the contemporary research is oriented to refining the categories Seeman proposed and not always by means of validated scales. In a study of teachers' feelings of alienation, for example, Jeffreys Brooks et al. (2008) carried out interviews over a two-year period. Content analysis of the data showed that, among the interviewees, not only were conceptualizations of the dimensions interrelated, but the salience of different dimensions shifted under changing circumstances. It has also been shown that dimensions of alienation could serve in analyses of popular jokes (Mauldin, 2008).

Both quantitative and qualitative analyses have been applied to studying the nature of the possible spread of alienation through the expanding uses of new digital technologies. Douglas Kellner (2005) has argued that there are connections between alienation and responses to digital technologies that range from 'technophobia' to 'technophilia.' Contact with digital technologies has been analyzed structurally to show that they are likely to foster new forms of alienation. But understood dialectically, they can also provide new realms of agency and meaning. Research of these possibilities often makes use of questionnaires (see Gunter et al., 2002 for an evaluation of the possibilities; Pietilä, 1970 for an early study of alienation and the mass media). More specifically, research of reactions to digital media has led to revised meanings of alienation as the degradation of political literacy, i.e., losing the capacity for independent, critical thought, and being likely to agree with the latest thing read or heard (Hassan, 2003).

Since the end of the twentieth century, there has been increasing interest in understanding alienation so as to derive meaningful ways of promoting dis-alienation. This research focuses on detailed examinations of extremes of consumption to the point of carnivalization – modes of intentional self-liberation which, paradoxically, are likely to lead to further enslavement (Langman, 2011). A more hopeful line of research in that direction is research into the structural foundations of social movements (Langman, 2013). At the same time, research based on a perception of alienation as a state of self-awareness is pursued in the investigations of teaching and learning in education, in ethnic and race relations, and in relation to persistent problems in the organization of work.

This article is a revision of the previous edition article by M. Seeman, volume 1, pp 385–388, © 2001, Elsevier Ltd.

Abstract

Subjective alienation is the sense of being separate from oneself or others. Perceived powerlessness is the main type of alienation because it is a separation from important outcomes in one's own life. Self-estrangement is a type of powerlessness related to one's work, and the closest conceptually to Marx's ideas of alienation. Others include social isolation, normlessness, and meaninglessness. Mistrust is a recently identified type of alienation. It is a type of social alienation more profound than social isolation. We focus on perceived powerlessness and mistrust: the concepts and measures, social causes, and emotional consequences. The major social causes include socioeconomic status (education, income, and work); gender; age; and neighborhoods. We conclude with directions for future research on contextual causes of mistrust and powerlessness.

Subjective Alienation

Subjective alienation is the sense of detachment or separation from oneself and society (Seeman, 1959, 1983; Fischer, 1976: Mirowsky and Ross, 2003). In 1959, Seeman identified five types of subjective alienation: powerlessness, self-estrangement, social isolation, normlessness, and meaninglessness. Over the years, Mirowsky and Ross expanded and modified these initial components to include powerlessness, self-estrangement, social isolation, normlessness, meaninglessness, and mistrust. Powerlessness is the essence of subjective alienation because it is separation from oneself. People with a sense of powerlessness think that they have little control over meaningful events and circumstances in their lives. Self-estrangement is a type of powerlessness related to work. People who are estranged from work do not see their work as an expression of themselves, but rather something given over to the control of others. Normlessness is the perceived gap between goals and legitimate means to achieve them, with the resulting dissociation from socially approved norms governing behavior. Social isolation is the sense of separation from others. It is the sense of not having anyone who is someone to you and not being someone to anyone. Meaninglessness is the sense that one's life has no meaning or purpose. Mistrust is suspicion of others.

Powerlessness and normlessness both are signal gaps in personal achievement: the cognitive awareness of a discrepancy between one's goals and one's ability to achieve them. Powerlessness is a more profound sense of alienation than is normlessness, since normlessness is the perceived gap between goals and legal, approved and normative means whereas powerlessness is the perceived gap between goals and *any* available means. A person who feels powerless feels helpless to achieve desired ends through any means, whereas a person who feels normless thinks that socially unapproved behaviors could be effective in achieving goals.

Social isolation and mistrust both signal social alienation, or a sense of separation from others. People who are socially isolated are detached from networks of affection, aid, and reciprocity. The opposite of isolation is commonly called social support, which is the sense of being cared for and loved, esteemed and valued as a person, and part of a network of communication and obligation. This concept of isolation and support differs radically from Seeman's original definition of isolation as assigning low value to mainstream society's goals or beliefs, sometimes called 'cultural estrangement.' Although Seeman originally excluded "the warmth, security, or intensity of an individual's social contacts" from his definition of isolation, it is precisely this meaning that has greatest currency today, and that is most important in research.

Mistrust goes beyond a sense of separation from others to one of suspicion of others. It is the cognitive habit of interpreting the intentions and behavior of other people as unsupportive, self-seeking, and dishonest. Mistrusting individuals do not have faith in other people; they think others are out for their own good and would willingly harm them in pursuit of their goals. They therefore believe it is safer to keep their distance from others. Although Seeman did not include mistrust as a type of subjective alienation, Mirowsky and Ross consider mistrust a profound form of social alienation.

Subjective alienation has social causes and consequences for well-being. Most empirical research examines consequences for psychological distress, defined as painful psychological or emotional symptoms such as depression, anxiety, and anger; and for physical well-being. Theoretically, subjective alienation is the cognitive link between reality and distress. It is the subjective reflection of social conditions of objective powerlessness, structural inconsistency (or a gap between goals and means to achieve them), an inability to achieve goals, alienated labor, dependency, threat, and the absence of supportive, trusting, nonpredatory relationships.

Perceived powerlessness, or a separation from oneself, is the essence of subjective alienation. Most research focuses on powerlessness (including some on self-estrangement) and social isolation, with the newest research focusing on mistrust; less research measures or examines normlessness or meaninglessness. Thus, we next go into some detail about the concept of powerlessness.

Perceived Powerlessness

The Names and Faces of Powerlessness

In sociology, the concept of perceived powerlessness vs control is the core type of subjective alienation (Seeman, 1959).

Powerlessness is the separation from important outcomes in one's own life; or an inability to achieve desired ends. Perceived powerlessness is the awareness of this gap between goals and means. Perceived powerlessness is the learned and generalized expectation that one has little control over meaningful circumstances in one's life. On the other end of the continuum, the sense of personal control is the belief that outcomes are contingent on one's own choices and actions; it is the cognitive awareness of a link between efforts and outcomes. (Mirowsky and Ross, 2003; Seeman, 1983). The importance of perceived control vs powerlessness is recognized in a number of social and behavioral sciences, where it appears in several forms with various names, notably mastery (Pearlin et al., 1981), personal autonomy (Seeman, 1983), the sense of personal efficacy (Downey and Moen, 1987; Gecas, 1989), self-directedness (Kohn and Schooler, 1982), agency (Thoits, 2006), and instrumentalism (Wheaton, 1980), and at the other end of the continuum, external locus of control (Rotter, 1966), fatalism (Wheaton, 1980) and perceived helplessness (Elder and Liker, 1982).

Locus of Control

In cognitive psychology, the concept of perceived powerlessness vs control can be traced to social learning theory, and Rotter's concept of locus of control (1966). Belief in an external locus of control is a *learned*, generalized expectation that outcomes of situations are determined by forces external to one's self such as powerful others, luck, fate, or chance. The individual believes that he or she is powerless and at the mercy of the environment. Belief in an internal locus of control (the opposite) is a learned, generalized expectation that outcomes are contingent on one's own choices and actions.

Both Rotter (1966) and Seeman (1959) recognized that perceived powerlessness – the major form of subjective alienation – and external locus of control were related concepts. In fact, Rotter derived the concept of locus of control from the sociological concept of alienation, stating "the alienated individual feels unable to control his own destiny" (1966: p. 263).

The Sense of Personal Control

Based on these traditions, Mirowsky and Ross (1991, 2003) clarified and developed the measure of the sense of personal control vs powerlessness. The sense of personal control corresponds to the personal control component of Rotter's locus of control scale, which includes questions like "when I make plans I can make them work" or "I have little influence over the things that happen to me." The concept of personal control refers to *oneself*, not others, and it is *general*, not realm specific. Thus, unlike Rotter's locus of control scale, it excludes beliefs about the control others have over their lives and realm specific control, like political control, from the concept. For instance, they do not consider questions from the Rotter scale like "the average citizen can have an influence in government decisions" or "there will always be wars" to be measures of the sense of personal control since they do not refer to oneself, and they are realm specific.

Responses to questions about personal control capture the concept of interest, and two other cross-cutting concepts – the tendency to agree and self-defense. Some people tend to agree with statements irrespective of content. Agreement tendency can make it appear as if internal and external controls are uncorrelated. Some people are more likely to believe that they control the good outcomes in their lives than that they control the bad ones (self-defense); others take more responsibility for their failures than for their successes (self-blame). Agreement tendencies and the tendency toward self-defense or self-blame cross-cut the concept of interest and bias measures unless they balance agreement and defense (Mirowsky and Ross, 1990a, 1991, 1996). Thus, the Mirowsky–Ross measure of personal control vs powerlessness balances defensiveness and agreement tendencies to achieve an unbiased measure. It is a two-by-two index that balances statements about control with those about lack of control, and statements about success (good outcomes) with those about failure (bad outcomes). The Mirowsky–Ross sense of personal control vs powerlessness scale (1991) asks respondents how much they agree with the following statements:

Internal

Control over good:
1. "I am responsible for my own successes"
2. "I can do just about anything I really set my mind to"

Control over bad:
3. "My misfortunes are the result of mistakes I have made"
4. "I am responsible for my failures"

External

Powerless over good:
5. "The really good things that happen to me are mostly luck"
6. "There's no sense planning a lot – if something good is going to happen it will"

Powerless over bad:
7. "Most of my problems are due to bad breaks"
8. "I have little control over the bad things that happen to me"

Learned Helplessness and Self-Efficacy

Two other traditions from behavioral psychology and attribution theory in psychology are also related to the sense of powerlessness vs control: learned helplessness and self-efficacy. The behavior of learned helplessness results from exposure to inescapable, uncontrollable negative stimuli and is characterized by a low rate of voluntary response and low ability to learn successful behaviors (Seligman, 1975). Although learned helplessness is a behavior, not a belief, in humans, there is a link between external control (a cognitive orientation) and learned helplessness (a conditioned response): the *perception* that reinforcement is not contingent on action.

Self-efficacy focuses on the individual's belief that he or she can (or cannot) effectively perform a specific action in a particular context (Bandura, 1986). The sense of personal control, in comparison, is more general, with universal application to many contexts. The degree to which people think they can or cannot achieve their goals, despite the specific nature of the actions required, has applies to many circumstances. More importantly, the sense of personal control may be the root of self-efficacy. A person with a high sense of personal control will likely try other actions if their current repertoire of behaviors is not working. New behaviors may successfully

obtain desired goals, which may in turn increase the perceived ability to shape other events and circumstances in life.

Emotional Consequences of Powerlessness

Compared to the belief that outcomes are determined by forces external to oneself, belief in personal control is associated with low levels of psychological distress (Pearlin et al., 1981; Mirowsky and Ross, 1990b, 2003; Wheaton, 1980). In fact, of all the beliefs about self and society that might affect distress, belief in control over one's own life may be the most important (Mirowsky and Ross, 2003). Perceived powerlessness is significantly associated with depression, anxiety, and anger, but its influence on depression is greatest. If one cannot influence conditions and events in one's own life, what hope is there for the future? In addition to its direct, demoralizing effect, the sense of not being in control of the outcomes in one's life diminishes the will and motivation to solve problems or avoid them, so disadvantages accumulate.

Heuristics in Psychology and Sociology

Ideally, social psychologists who study the links between social structural conditions, perceptions of control, and emotional outcomes, will synthesize the strengths of psychology and sociology – as did Rotter and Seeman–while avoiding the pitfalls. Each discipline has a heuristic, or working assumption, which greatly simplifies reality to provide a base from which to proceed with research. In the extreme, psychology assumes that beliefs come out of people's heads without reference to social conditions, whereas sociology assumes that there is nothing *but* social structure. Sociologists too often discount the ways in which perceptions mediate the effects of social position on well-being; psychologists too often discount the influence of social structure on perceptions.

Social Structural Causes of Perceived Control vs Powerlessness

In the United States, average levels of perceived control are high, and they vary systematically with positions of objective power (Mirowsky et al., 1996).

Objective Power and Perceived Control

Belief in external control is the learned and generalized expectation that one has little control over meaningful events and circumstances in one's life. As such, it is the cognitive awareness of a discrepancy between one's goals and the means to achieve them. Theoretically, social structural positions indicative of objective powerlessness, including dependency, disorder, structural inconsistency, and alienated labor, increase the probability of this discrepancy and thus increase perceived powerlessness (Avison and Cairney, 2003; Mirowsky and Ross, 2003).

Beliefs about personal control are often realistic perceptions of objective conditions. An individual learns through social interaction and personal experience that his or her choices and efforts are usually likely or unlikely to affect the outcome of a situation. Failure in the face of effort leads to a sense of powerlessness, fatalism, or belief in external control, beliefs that can increase passivity and result in giving up. Through continued experience with objective conditions of powerlessness and lack of control, individuals come to learn that their own actions cannot produce desired outcomes. In contrast, success leads to a sense of mastery, efficacy, or belief in internal control, characterized by an active, problem-solving approach to life (Wheaton, 1980, 1983; Mirowsky and Ross, 1983, 2003).

Sociological theory points to several conditions likely to produce a belief in external control. First and foremost is powerlessness. Defined as an objective condition rather than a belief, it is the inability to achieve one's ends or, alternatively, the inability to achieve one's ends when in opposition to others. The second is structural inconsistency, which is a situation in which society defines certain goals, purposes, and interests as legitimate and desirable and also defines the proper procedures for moving toward the objectives but does not provide adequate resources and opportunities for achieving the objectives through legitimate means. The third is alienated labor, a condition under which the worker does not decide what to produce, does not design and schedule the production process, and does not own the product. The fourth is dependency, a situation in which one partner in an exchange has fewer alternative sources of sustenance and gratification than the other. The fifth is role overload, a situation in which expectations of others imply demands that overwhelm the resources and capabilities of the individual. The sixth is threat – the potential for danger and harm in one's environment such as a neighborhood disorder. Although these conditions are not exhaustive, they all point to the generative force of various forms of social power. In looking for the sources of perceived powerlessness, researchers have looked for variables associated with conditions of powerlessness, structural inconsistency, alienated labor, dependency, role overload, and threat.

Among the major sociodemographic correlates of the sense of personal control are socioeconomic status, including education, income, work, and unemployment; neighborhood disadvantage and disorder; and gender and age.

Socioeconomic Status

Most research on the social structural correlates of perceived control vs powerlessness looks at socioeconomic status. Looking at specific components of socioeconomic status (SES) separately, education, family income, personal earnings, economic hardship, job status, and control at work each decrease the sense of powerlessness, adjusting for the other components (Mirowsky and Ross, 2003).

Education develops effective capacities on many levels. First, in formal education one encounters and solves problems that are progressively more difficult, complex, and subtle. The process of learning builds confidence and self-assurance, even if the things learned have no practical value. Those things, however, often do have practical value. Education also instills the habit of meeting problems with attention, thought, action, and persistence. It develops the general habits and skills of communication and analysis, plus those which are tailored to an occupation. Education develops the ability to solve problems on all these levels, and the ability to solve problems increases control over events and outcomes in life. Finally, education serves as an avenue to good jobs and high incomes. Thus it marks the social power

that helps provide control over circumstances of life (Mirowsky, 1995; Mirowsky and Ross, 1998, 2007; Schieman, 2001; Schieman and Plickert, 2008).

In school, academic achievement as measured by grades and test scores increases the sense of control between 8th and 12th grades, and the sense of control in turn boosts academic achievement (Ross and Broh, 2000). In contrast, although success in school also increases self-esteem, self-esteem, in turn, has no significant impact on academic achievement. Young adults who stay in school see an increase in the sense of personal control between the ages of 14 and 22 that persists at least to age 35, whereas those who drop out of high school do not (Lewis et al., 1999). Finally, young adults whose parents are well educated have higher levels of personal control and mastery than the children of poorly educated parents (Lewis et al., 1999).

Education acts like a stored resource, enhancing the development of personal control in young adulthood and slowing its erosion in old age (Mirowsky and Ross, 2007). Compared with the college educated, persons with a high school degree have a lower sense of control which peaks at a lower level and at a younger age, and then declines rapidly in older age. Among those with a college degree, the sense of control starts high, rises in young adulthood, stays high in middle age, and declines less in old age. The most disadvantaged life course trajectory of control is that among persons who have not finished high school. Their sense of control starts low, and never increases in young adulthood. In fact, it begins declining early, stays low, shows a little upturn around retirement (maybe from oppressive jobs), and then declines again to the lowest level of any group (Mirowsky and Ross, 2007).

Jobs are important for a number of reasons. Low-status jobs produce a sense of powerlessness because the job, and the opportunities and income it provides, are seen as barriers to the achievement of life goals (Wheaton, 1980). Jobs that are substantively complex (especially in work primarily with information and people rather than with things) increase the sense of personal control and psychological self-directedness (Kohn, 1976; Kohn and Schooler, 1982). Jobs that provide autonomy – freedom from close supervision and participation in decision-making – increase the sense of personal control (Bird and Ross, 1993; Ross and Mirowsky, 1992). Creative, nonroutine work that allows people to solve problems, learn new things, and engage in a variety of tasks also increases the sense of control (Ross, 2000). Creative and autonomous work each have independent effects on personal control, and, further, they explain the effect of working with people and data on the sense of control (Ross, 2000). Together substantively complex, nonroutine, creative, and autonomous work signals control over one's own work, which Kohn and his colleagues call occupational self-direction. Occupational self-direction – rather than ownership of the means of production or control over the labor of others – increases psychological self-direction (Kohn, 1976; Kohn and Schooler, 1982; Kohn et al., 1990). Job latitude, like occupational self-direction, includes autonomous decision-making and nonroutine work, and it significantly increases perceived control (Seeman et al., 1988). Job disruptions such as being laid off, downgraded, fired, or leaving work because of illness decrease the worker's sense of mastery, partly by lowering income and economic hardship (Pearlin et al., 1981).

Self-Estrangement and Alienated Labor

Self-estrangement is a specific type of powerlessness related to work. It is the sense that one's work is separate from oneself. In sociology, it can be traced to Marx's discussion of alienated labor. Marx was concerned about the impact of wage labor and factories on the quality of life. He argued that in working for someone else the laborer belongs to another person and not to himself. The work is a means of satisfying other needs rather than satisfying in itself; external rather than part of his or her nature; imposed rather than voluntary. Workers deny themselves in work rather than fulfill themselves. Marx argued that alienated labor makes the worker physically exhausted and mentally debased rather than developing his or her mental and physical energies. Thus, alienated labor produces a sense of misery rather than well-being. Alienated labor is the condition in which the worker does not decide what to produce, does not design the production process, and does not own the product. Self-estrangement is the sense of being separate from that part of one's thoughts, actions, and experiences given over to the control of others; of work being foreign to oneself rather than an expression of oneself. Work is seen as drudgery. There is no intrinsic gratification in work, and any rewards lie outside the activity itself (such as pay). There is no pride in work because the work is not a creative expression of oneself; thus the opposite may be called creative work (Mirowsky, 2011; Mirowsky and Ross, 2003).

Gender

Theory suggests that women have a lower sense of control over their lives than men as a result of social stratification and inequality: economic dependency, restricted opportunities, role overload, and the routine nature of housework and women's jobs. Women are more likely to do unpaid domestic work; men are more likely to work for pay. Compared to not working for pay, employment is associated with status, power, economic independence, and noneconomic rewards, for both men and women (Bird and Ross, 1993; Gove and Tudor, 1973). Both economic dependency and the disconnection between work and rewards decrease perceived control among unpaid domestic workers compared to paid workers (Ross and Mirowsky, 1992; Bird and Ross, 1993). Elder and Liker (1982) found that elderly women who had taken jobs 40 years earlier, during the Great Depression, had a higher sense of self-efficacy and lower sense of helplessness than women who remained homemakers.

Women's paid work is also more alienating than men's. Ross and Wright (1998) examined gender differences in four dimensions of work alienation – routine, nonautonomous, estranged, and isolated work; and the ways in which work alienation shapes subjective alienation, measured as the sense of powerlessness vs control. Women's work is more objectively alienating than men's, and these work characteristics shape people's sense of personal control. Nonroutine work, including task variety and problem-solving; autonomous work, including decision-making autonomy and freedom from supervision; fulfilling work; and nonisolated work all significantly positively affect the sense of personal control.

Work and Family Interactions

Overall, the employed have significantly higher average perceived control than do homemakers. Not all jobs are alike, however; nor are all household contexts of employment. Critical combinations of low pay, nonautonomous working conditions, and heavy family demands (conditions faced disproportionately by women) may negate the positive influence of employment on control (Ross and Mirowsky, 1992). Job autonomy, earnings, responsibility for household work, and other family income combine to make the association between employment and the sense of control greater for most men than for most women. Men have higher autonomy and earnings, less responsibility for household work, and lower amounts of other household income. Because of the differences in these factors, employment increases the expected sense of control most for married males, followed by nonmarried males, then nonmarried females, and finally married females. For married women, the typical combination of low pay, low autonomy, high responsibility for household chores, and high family income other than personal earnings nearly negates the positive association between employment and the sense of control.

The gender gap in perceived control is much greater for older persons than for younger. Compared with their male counterparts, older women face more educational, employment, economic, and health disadvantages than do younger women. Older people have lower levels of personal control than do younger, and this is especially true for women. Older women are more disadvantaged than younger because they experienced a lifetime of disadvantages in work and economic conditions that cumulated with age, and because women in older generations had fewer employment and educational opportunities and less equality in unpaid work at home than do younger women. The dynamics of aging, the differences among cohorts, and the link between the two combine to predict more gender equality among young adults than older.

Age

Research using large representative samples of persons across the full range of adult ages, from 18 to 90, shows that older adults have a lower sense of control than do younger adults, and that perceived control decreases with age at an accelerating rate (Mirowsky, 1995; Schieman, 2001; Turner and Lloyd, 1999). Slight increases in young adulthood seen in cross-sectional studies are actually larger when cohort differences are taken into account: control increases in young adulthood and then declines at an accelerating rate as people age into their sixties, seventies, and eighties (Mirowsky and Ross, 2007). Perceived powerlessness in old age results from increasing levels of physical disability and poor health, widowhood, and retirement, all of which are associated with aging (Mirowsky, 1995; Ross and Drentea, 1998). In addition to the effects of aging, older cohorts have lower levels of education than younger (Mirowsky, 1995; Mirowsky and Ross, 2007; Wolinsky and Stump, 1996; Wolinsky et al., 2003).

Neighborhood Disadvantage and Disorder

Neighborhood disadvantage and disorder are subjectively alienating (Ross and Mirowsky, 2009). Socioeconomically disadvantaged neighborhoods where few residents have college degrees, poverty, and mother-only families are common, home ownership is low, and unemployment is high, are prone to high levels of neighborhood disorder. Neighborhood disorder signals the potential for harm. Signs of disorder in one's neighborhood signify collective threat. Graffiti, noise, vandalism, dirty streets, public drinking, trash on the streets, and run-down buildings are cues. These cues tell residents about themselves and the world they live in. They indicate the breakdown of social control and order. Through exposure to threatening social conditions residents learn that they are relatively powerless. Lack of real control over desired outcomes – like a safe and nonthreatening place to live – leads to the perception that one is powerless to control one's life. (Geis and Ross, 1998; Ross, 2011; Ross and Mirowsky, 2009).

Mistrust

Neighborhood Disorder and a Structural Theory of Mistrust

Research on neighborhood disorder led to a new emphasis on mistrust as an important element of subjective alienation. Neighborhood disorder fosters mistrust. Mistrust arises from social conditions where resources and opportunities are scarce; and disorder, crime, threat, and danger are common. When resources are scarce, everyone competes for an inadequate pool, some individuals will try to take whatever they can get at other people's expense, and the consequences of losing what little one has will be devastating. Scarcity tempts individuals to victimize and exploit others. People with few resources compete for a limited pool. They generally seem willing to exploit others for personal gain. Victimization and exploitation appear inevitable and common, which lead to mistrust.

Trust is a belief in the integrity of other people. Trusting individuals have faith and confidence in other people and expect that they can depend on others (Rotter, 1980). Mistrust, the opposite of trust, is the cognitive habit of interpreting the intentions and behavior of others as unsupportive, self-seeking, and dishonest (Mirowsky and Ross, 1983). Suspicion of other people is the central cognitive component of mistrust. Trust and mistrust express inherently social beliefs about relationships with other people. They embody learned, generalized expectations about other people's behaviors that transcend specific relationships and situations (Barber, 1983; Kramer, 1999; Rotter, 1971).

In neighborhoods where residents report high levels of disorder, people face a threatening environment characterized by danger, crime, and incivility, which promotes mistrust. Residents may come to view those around them with suspicion, as enemies who will harm them rather than as allies who will help them. Mistrust makes sense where dangers abound (Ross et al., 2001). Mistrust, in turn, reduces social support and increases psychological distress, including depression, anxiety, and anger.

Social Support and Trust

Social support depends on trust. Social support is the opposite of social isolation – a type of alienation from others.

Social support is the commitment, caring, advice, and aid provided in personal relationships, the sense of being cared for and loved, esteemed and valued as a person, and part of a network of communication and obligation (Ross and Mirowsky, 1989; Mirowsky and Ross, 2003). Trust allows pairs of individuals to establish cooperative relationships whenever doing so is mutually beneficial. Coleman (1990) emphasizes trust as an element of social capital, because trusting social relationships help produce desired outcomes. People who trust others form personal ties and participate in voluntary associations more often than do mistrusting individuals (Paxton, 1999). Trusting individuals are themselves more trustworthy and honest and are less likely to lie and harm others so that they create and maintain environments of trustworthiness. They enter relationships with the presumption that others can be trusted until they have evidence to the contrary (Rotter, 1971, 1980). Because trusting individuals can form effective associations with others, the presumption of trust can be an advantageous strategy, despite the fact that expecting people to be trustworthy is risky.

Pathways Linking Neighborhood Disorder to Distress

Mistrust and powerlessness are the two big links between disorder and distress. Two other types of subjective alienation – normlessness and social isolation – are not. Neighborhood disorder promotes normlessness, but normlessness has little effect on distress. Social isolation has trade-offs at all stages. Social isolation is associated with increased depression, but decreased anger and anxiety. Furthermore, apart from a small indirect effect on isolation by way of mistrust, neighborhood disorder is associated with more social ties with others, not fewer. Powerlessness and mistrust consistently link neighborhood disorder to distress. Of the two, mistrust forms the larger link.

Mistrust was not originally included as a type of subjective alienation by Seeman despite the fact that it clearly fits the definition of subjective alienation as separation from oneself or others. Instead, social psychologists originally considered mistrust as an element of authoritarianism (along with inflexibility), but its importance for psychological distress may come from the deep alienation it represents (Mirowsky and Ross, 2003). Mistrusting individuals are not simply isolated from other people, they are deeply suspicious of others. Because they think other people are likely to harm them, they feel they cannot depend on others, turn to others when they need help, confide in others, or rely on them. To mistrusting individuals, any social interaction carries risk.

What are the sources of mistrust? Mistrust arises when conditions are threatening and resources are scarce. Neighborhood disorder indicates collective threat, which produces mistrust. Furthermore, disadvantaged individuals tend to live in disadvantaged neighborhoods with high levels of disorder. In addition to the collective effects, disadvantaged individuals with fewer resources have higher levels of mistrust. High levels of economic hardship, low levels of education, not being employed or married, and having been a victim of crime are all significantly associated with mistrust. The only exception to this pattern relates to gender. Men typically have more resources than women, yet men are significantly more mistrusting. In general, though, the powerless and disadvantaged are more mistrusting than the powerful and advantaged.

Powerlessness and Mistrust: Directions for Future Research

Mirowsky and Ross concluded that a low sense of control over one's own life creates the primary link between psychological distress and individual disadvantaged social statuses such as low education, economic hardship, unemployment, unstable employment, and poorly paid, tedious, routine, and oppressive jobs. Perceived powerlessness links individual socioeconomic disadvantage to distress. It is possible that mistrust creates a major link between psychological distress and collective disadvantage. Perceived powerlessness is the cognitive awareness of an inability to achieve individual goals. It is a separation from self – from important outcomes in one's own life. Mistrust represents social alienation – a separation from others. A promising direction for future research is the idea that neighborhood context is linked to distress by way of social alienation more than alienation from oneself. Social cues of disorder like people hanging out on the streets, drinking or taking drugs, making trouble, and heightening the sense of danger are cues about other people in one's neighborhood. Even the physical cues of neighborhood disorder like graffiti, vandalism, run-down buildings, and trash on the streets are ultimately cues about the activities of people in one's neighborhood, because a person broke the window or spray-painted the graffiti. The collective threat implied by disorder is created by other people, and may lead to the social alienation of mistrust more than to the personal alienation of powerlessness. Since the research by Ross and Mirowsky (2009) is the first attempt to link distress to neighborhood disorder through of a number of different types of subjective alienation future research should attempt to confirm or disconfirm this idea.

Abstract

Alienation is the feeling of an unnatural separation or a sense of radical disconnectedness. It is a feeling of homelessness and lacking roots and foundation. It is a feeling that one has little or no worth; it is a belief that life has no meaning. While the sense of alienation is found throughout history, it is found predominately in the West as a result of industrialization and the rise of modern capitalism.

Alienation: An Introduction

Alienation is the sense of unnatural separation or radical disconnectedness; it is a sense of homelessness and uprootedness. An alienated individual often believes that he or she lacks meaning or worth. Marx is usually credited with providing the most influential account of alienation, but its antecedents are found in Hegel. Moreover, Marx rejected the idealistic versions and instead developed a more economy-oriented account of self-alienation. Ferdinand Tönnies and especially Georg Simmel developed significant sociological explications of the concept of alienation and Karl Jaspers contributed important contemporary cultural analyses of it. Having been mentored by Jaspers (as well as by Martin Heidegger), Hannah Arendt returned to a more philosophical account of world alienation. Each of these twentieth century thinkers explored its crucial impact on modern culture.

Philosophical Alienation

It was in the 1960s that the concept of alienation became a popular subject. In his important and lengthy introduction to Richard Schacht's indispensable book *Alienation*, Walter Kaufmann explains how the notion of alienation came to be so popular. He suggested that it was a Cold War intersection between existentialism and Marxism and he traces it back to Erich Fromm's translation of Marx's *Economic and Philosophical Manuscripts of 1844*. These were first published in 1932 and were immediately recognized as providing a humanist conception of Marx, but World War II effectively made much discussion of it impossible. By the 1950s and 1960s the time was finally ripe for scholarly examinations of Marx's early writings. Kaufmann also points out that the young Marx was heavily influenced by Hegel and nowhere is this as evident as with the concept of alienation (Kaufmann, 1970: xvii–xxiii).

Georg Wilhelm Friedrich Hegel was the first scholar to utilize the notion of alienation, which he did in his *Phenomenology of Spirit*. This work is both brilliant and puzzling; it is brilliant in that Hegel sets himself the task to trace the forms of spirit throughout history. Hegel was not a historian, so he was not interested in historical accuracy per se. Instead, he sought to provide an ideal account of spirit in its historical manifestations. It is a puzzling work because of Hegel's audacity in writing it, and even more so in his choice of words. Translated into English Hegel's terminology verges on being strange; in German they seem somewhat better. This is because Hegel uses words in new and different ways; for example, he uses the term 'aufheben' to mean two almost contradictory processes. First, there is the sense of 'to cancel' and second, there is the sense 'to lift up.' By itself, the term seems not to make much sense; but when one understands that Hegel regards the process of the forms of the unfolding spirit as dialectical that it becomes more comprehensible. Accordingly, there is a process in which one form is countered by its opposite, and then both the one and its counterpart cancel each other out and then are together lifted up to the next stage in the process. Hegel's dual use of words is also found with respect to his notion of 'alienation' ('Entfremdung'), which is one of the most central terms of the *Phenomenology*. Richard Schacht notes that Hegel uses 'alienation' in two ways: first as 'separation' and second as 'surrender' (Schacht, 1970: 38, note 1; 43–44). Taken as a whole, the entire *Phenomenology* could be read as a treatise on alienation – the various stages in which humankind is alienated from itself. But, Hegel also devotes two specific sections to the notion of alienation.

In the lengthy section entitled 'Self-Alienated Spirit. Culture' Hegel writes of the alienation of the 'objective' essence and the 'subjective' self (Hegel, 1977: 295). By recognizing that there is something other than the subjective realm of faith, the self becomes alienated. The 'objective' realm of knowledge confronts the subjective belief in faith, which leads not only to doubt but also to the alienation of oneself as a natural being (Hegel, 1977: 297–298). On a more general level there is another process of alienation and opposition between the objective and 'self-less' state and the 'subjective' and 'selfish' striving for wealth (Hegel, 1977: 306, 313). While it seems obvious which side is 'good' and which side is 'bad,' Hegel suggests that this is only an apparent opposition and is part of 'pure culture' (Hegel, 1977: 316–317, 321). This opposition mirrors the opposition between faith and knowledge and leads to 'delusion and deception'; however, faith and enlightenment 'reconcile' at a certain level. This apparent reconciliation then provides the starting stage for the next stage of Hegel's dialectical process (Hegel, 1977: 335, 346).

In the *Phenomenology* there is an earlier section, which not only offers an explication of alienation, but one that will provide considerable material for Marx. This is the much

smaller section entitled 'Lordship and Bondage.' There are two 'individuals' who confront each other. This encounter is problematic because while they must acknowledge that there is another, this recognition leads to a struggle – who recognizes whom? This struggle is the struggle for the certainty of one's self – Hegel writes that only by staking one's life is freedom won (Hegel, 1977: 114). Of course, there can be only one 'winner,' the 'master' while the loser becomes the 'slave.' The master now has consciousness of one's own self, thus seems superior to the slave, who must now be conscious of the master. However, this superiority is illusionary; the slave engages in work, and by working on things he becomes aware of himself as a self-conscious being. In contrast, the master who does not work knows only the desire for things; thus the master is dependent on the slave. It is the activity of work that defines and raises up the slave, while the lack of activity and the burden of desire subjugates the master. It is Hegel's notion of work that will become important for Marx's notion of man.

Hegel's conceptions of alienation are intriguing but they suffer from difficulties. His dual senses of alienation cause confusion – from Hegel's general philosophical point of view they seem to be correct, but when viewed specifically they seem to be contradictory. More importantly, Hegel could not solve the problem of alienation because he abstracted and generalized both 'work' as well as 'needs' (Löwith, 1941: 350–352). Despite the importance of Hegel's account of alienation, it remained largely neglected until 1932 with the publication of Marx's *Economic and Philosophical Manuscripts* (Schacht, 1970: 73).

Economical Alienation

Karl Marx is best known for his writings on capitalism and labor; he specialized in discussing material conditions and modes of productions, of class, and value. However, as Karl Löwith pointed out, Marx was not interested in general conditions. Nor was he interested in theory and contemplation; rather, his concern was with practice and action. This is especially true regarding Marx's opinion of Hegel's concept of alienation. While he acknowledged its importance, Marx's major criticism was that it was too philosophical and too abstract (Löwith, 1952: 71). In contrast to Hegel's concern with abstract spirit, Marx's focus is on man as such. Bertell Ollman also noted that Marx's major concern was with the nature of man, and in Ollman's view, that meant dwelling on the nature and effects of alienation (Ollman, 1976: xi). The concept of alienation is, as István Mészáros has suggested, a key concept that can be found throughout Marx's writings (Mészáros, 1972: 66). However, as Allen Wood has argued, it has two distinctly different roles to play. In Marx's early writings, the concept of alienation is crucial for three reasons: Marx discusses the irrationalities of modern life; he argues that one of the most problematic of these irrationalities is found in modern labor; and this type of labor is historically determinant and also transitory. Alienation is part of the path of human development. Wood goes on to suggest that while Marx's early conception of alienation is important, it lacks persuasion because it is "too vague and metaphorical to perform the explanatory function that Marx tries to assign it" (Wood, 1981: 71). Wood argues further that Marx's later conception of alienation succeeds because he no longer tries to use alienation as an explanation; rather, he uses it as a description. Whether these accounts fail or succeed, is not the issue here; the issue here is simply to provide an overview of Marx's conceptions. Marx's early account of alienation can be broken down into four different variations of alienation: between the individual and one's labor; between the individual and one's products; between the individual and one's fellow human beings; and between the individual and one's species. Marx believed that, unlike political economy accounts, his account would explain man's condition. And, unlike the accounts of political economists, which begin with a 'legendary primordial condition' Marx will begin his account with a *contemporary* fact (Marx, 1964: 120–121).

Marx's notion of labor is crucial to his entire thinking because it is a fundamental fact of human life: humans must produce (Schacht, 1970: 87; Mészáros, 1972: 76–77, 80). Because labor is one of the most important facets of human life, Marx suggests that alienated labor is the most important of all of the types of alienation.

Marx begins with an economic fact: the more wealth the worker produces, the poorer the worker becomes. In other words, the human world is devalued as the value of the world of things increases. This is because the labor of the worker not only produces goods; but it also produces the worker as a commodity (Marx, 1964: 121, 129). This may not say much by itself, but Marx clarifies this by insisting that the worker produces the object, which is an alien one – one which is independent and opposed to the worker. This is the 'objectification of labor,' which makes the laborer subservient to the object – hence, the alienation (Marx, 1964: 121–122). Marx emphasizes the growing alienation; the greater the worker's activity the less he possesses, the greater the product the more he is diminished. The object exists independently of the worker who made it; it is now an alien and autonomous power (Marx, 1964: 123–124). In a moving passage Marx writes: "the more the worker produces the less he has to consume; the more value he creates the more worthless he becomes; the more refined his product the more crude and misshapen the worker; the more civilized the product the more barbarous the worker …." (Marx, 1964: 124).

Marx moves from the type of alienation that results from the product to the type that comes from the process; that is, from the activity of the work itself. Many scholars writing on capitalism contend that 'formally free labor' was a necessary prerequisite for the development of modern capitalism; which would have been impossible to develop with 'slave labor.' Marx takes the opposite view; that in capitalism, work is not voluntary but is imposed – it is 'forced labor.' The worker must work for another, not for himself. The worker works only in order to satisfy needs and in work the worker feels alienated. It is only during those few hours at home that the worker has the sense of leisure and feels less alienated (Marx, 1964: 125–126).

The third and fourth types of alienated labor can be examined together because they no longer pertain to just the individual and its object; now it is concerning the species and other members of the human race. Marx's basic point is that humans are not isolated creatures but exist in a social setting. Accordingly, the alienation of one's self is reflected in the alienation to other human beings (Marx, 1964: 129). Ollman explains

this: first that this form of alienation diminishes, if not eliminates, the human advantage over other animals; and second it leaves 'man as a rump of himself.' Some commentators contend that alienation causes people to lose the capacity to be fully human, while others maintain that alienation causes the worker to lose one's entire sense of being human (Ollman, 1976: 151–152; Mészáros, 1972: 146–149).

Marx traces the problems of alienation to two things: money and private property (Marx, 1964: 121, 131). Money is a problem because it produces a whole system of alienation – which includes monopoly and competition, labor and private property, and "the whole system of money" (Marx, 1964: 121). Private property is a problem because it is a direct result of alienated labor. But, it is not only the basis and cause of alienated labor; alienated labor becomes the cause of private property (Marx, 1964: 132). The elimination of private property will emancipate the workers, thus eliminating alienation. Marx does not expand upon this topic; the manuscript suddenly ends (Marx, 1964: 133–134). We do know that Marx was convinced that there will be a revolution and the result will be socialism. In this socialist paradise there will be no state, no classes, and even no labor: in "the realm of freedom," "labor will be abolished" (Arendt, 1968: 22, 24). And, with labor having been abolished, alienation will also disappear.

There is considerable disagreement about the nature of Marx's conception of alienation and his notion of how it will be eliminated; but there is virtually no disagreement about its massive influence. Many scholars would disagree about how rigorous this conception is; but they would probably all agree that every subsequent account of alienation is in some way indebted to that of Marx.

Sociological and Cultural Alienation

Although Ferdinand Tönnies had engaged in an intensive study of Marx, he never developed a theory of alienation. Nonetheless, his sociological writings often indicate a great awareness of the problem of alienation in modern culture. That is why his distinction between 'Gemeinschaft' ('community') and 'Gesellschaft' ('society') is so important. In *Gemeinschaft und Gesellschaft* Tönnies contrasts the healthy, essential, and organic older community with the unhealthy, arbitrary, and artificial modern society. The community was an 'economic–communistic arrangement' but the society is based exclusively on money and rational exchange (Tönnies, 1991: 31, 39, 44). Tönnies quotes Marx's claim that in the capitalistic system everyone must possess an encyclopedic knowledge of goods; but he also quotes Adam Smith's observation that a merchant "is not necessarily a citizen of any particular country" (Tönnies, 1991: 48). Everything and everyone in society is reduced to a calculable system of intentions, means, and goals (Tönnies, 1991: 93). Modern society is an alienated society; everyone is cut off from one another. It resembles Hobbes' state of nature where there is a "war of all against all" (Adair-Toteff, 1995: 60). There is little question that Tönnies approves of the old community and disapproves of modern society: the great metropolis is the place of capital, money, and artificial society, but the country village is the home for family and friends (Tönnies, 1991: 212). The village is the place for closeness and togetherness; the large city is the place for alienation and cold power (Tönnies, 1991: 215–217). The village is the place of the 'security blanket,' but it lacks the precision that makes progress possible. Moreover, it is not as idyllic as Tönnies makes it seem: its 'conformity and uniformity' could be just as stifling and alienating as the modern city (Segalman, 1981: 43–47).

Where Tönnies recognized alienation as being the problem for one of the two major sociological groups, Georg Simmel saw alienation as being the great problem for the individual. Simmel regarded modern life as being full of conflict and tragedy (Simmel, 1918: 14, 35). In the past, the age-old problem of alienation from God had been minimized to some extent by religious faith and tradition; Simmel writes of the mystical union of a Meister Eckhart: "my eye and God's eye is one eye" (Simmel, 1989: 14). However, modern culture had lost the power of belief and rejected the weight of tradition; instead, it rushed into a restless rationality (Simmel, 1986: 199). Simmel was one thinker who truly captured the tragic spirit of oppositions – of being and becoming, of subject and object, of form and content, of reality and illusion (Simmel, 1986, 1989: 195). And, he was certainly one of the most poetic thinkers to express the feeling of helplessness, of being lost, and of the boundless sense of strangeness (Bauer, 1962: 20). Simmel described the modern epoch as one, which had become 'overripe and tired,' which was filled with discrepancies and discordances – what he called a "tragedy of culture" (Simmel, 1986: 203, 208, 210, 215).

Simmel offers a more specific account of alienation toward the end of *The Philosophy of Money*, as helpfully noted by Jorge Arditi. Unfortunately, instead of focusing on this he concentrates on Simmel's emphasis on irrationality (Arditi, 1996: 94–95). What Arditi does do, is to hint at the prominence that the notion of distance plays in Simmel's thinking (Arditi, 1996: 990). It is found in the section of *Soziologie* devoted to the stranger; it is the stranger's burden to be physically removed from others. Because of distance, he does not share our roots, and by implication he does not share our values. In short, the stranger is not one of us (Simmel, 1971: 145). It is also found in the short work on cities; while the city is crowded with people, each suffers in isolation. This 'mutual strangeness and revulsion' arises because of the infinite complexity of city life (Simmel, 1971: 331). This pervasive 'conflict with human beings' is rooted in the relentless pursuit of money; one becomes a mere 'cog' (Simmel, 1971: 326–327, 337). Above all, the notion of distance plays the most significant role in Simmel's discussion of alienation in the *Philosophie des Geldes*. In the chapter *Style of Life*, Simmel emphasizes that calculation is the defining characteristic of modern culture. Everything is measured, weighed, and exactingly calculated which leads to a growing discrepancy between individual and object. The growing separation between worker and the means of production is mirrored in the increasing distance between the 'creating personality' and the 'created artifact' (Simmel, 1900: 472, 478, 486). Simmel regards this emphasis on 'form, function, and the quantitative' as part of the growing objectification of culture, with the resulting decrease in the importance of the person (Simmel, 1900: 505).

Friedrich Nietzsche did not set out to write explicitly about alienation; however, he traced the inversion and alienation of natural values, which he believed led to the perversion and decline of Western civilization. Nietzsche's unusual task as set out in the *Genealogy of Morals* is to examine the 'value of values' (Nietzsche, 1999c: 253). He examines how the terms 'good' and 'bad' were transformed into 'good' and 'evil' (Nietzsche, 1999c: 261–265). Originally, it was the natural domination of the strong over the weak, the elites over the masses. As he described it in *Beyond Good and Evil*, the noble ones sought danger and believed in risk, but, with the 'slave uprising' of the Jews, followed by Christian belief in salvation, and by the platonizing of Christianity, these values were inverted (Nietzsche, 1999b: 82). Now, what was valued was 'modesty' and 'obedience' (Nietzsche, 1999c: 281, 287). And, now the operative words were 'guilt,' 'conscience,' and 'duty' (Nietzsche, 1999c: 300–306, 318–321, 330–332). Instead of the natural and instinctive enjoyment of the body and the senses, Christianity introduced the ascetic denial and denunciation of all things worldly; as Nietzsche says 'living against life' (Nietzsche, 1999c: 342–344, 361, 365). This is an alienating sickness of weakness, a sickness of suffering against all that is high and noble. It is the herd instinct against the individual (Nietzsche, 1999c: 370–373, 384). In the preface to *Zarathustra*, Zarathustra speaks of man's overcoming his limitations and becoming 'der Übermensch,' but he is met with laughter and derision by the crowd. They reject the idea that God is dead; instead they believe in a 'herd without a shepherd.' To the 'last men' the world has become smaller and warmer, and they believe that they have found 'happiness' (Nietzsche, 1999a: 20). What they have found is the belief in inverted values and alienated life.

Nietzsche was not content to diagnose the problems with the Judeo-Christian beliefs; he also wanted to point to a way to overcome these self-inflicted problems. The main source for Nietzsche's path to health is found in *Thus Spake Zarathustra*. Nietzsche points to the coming of the 'Übermensch,' the one who 'overcomes' one's self. In the section on *The Stillest Hour*, a 'voice without a voice' approaches Zarathustra and urges him to 'become like a child' and to accept what is in him (Nietzsche, 1999a: 187–190). Later, Zarathustra is told 'who he is and who he must become': the teacher of the doctrine of the eternal recurrence (Nietzsche, 1999a: 275). It is the rejection of the illusory promise of the afterlife and is the embracing of the here and now, in its greatness and its smallness (Nietzsche, 1999a: 275–277).

In *Reason and Existence*, Karl Jaspers points to the most important point in Nietzsche's philosophy – "God is dead" (Jaspers, 1947: 15). With the death of God we are free to reject alienation; to become who we are. It is not surprising that Jaspers wrote one of the most significant books on Nietzsche (Jaspers, 1981). He not only brought a philosopher's way of examining Nietzsche's theories, but his training as a psychiatrist helped him understand Nietzsche as a troubled individual. In turn, this helped Jaspers to comprehend the individual's sense of alienation in the modern world. Following his friend and mentor Max Weber, Jaspers believed that rational calculability and modern technology defined the twentieth century (Jaspers, 1999: 4). People were rarely only individuals; instead they belonged to the masses. Unfortunately, as Jaspers indicated, when a person is part of a mass, he or she is no longer a person. As part of the masses, there is no real existence and there is no real faith (Jaspers, 1999: 36–37). Instead, modern existence is dominated by advertisements; everything must be a 'sensation.' There is the constant overcoming of daily life through newspapers, radio, film, and travel. There is also the permanent separation between work and enjoyment (Jaspers, 1999: 42–43). One is ripped from one's roots and has lost one's essence. The masses are dominated by the faceless bureaucracy, which is hidden in a 'ghostlike invisibility.' In such a life one has mostly lost the sense of real responsibility. What one does have is fear and anxiety ('angst') for the future; and this 'angst' manifests itself in physical and psychical illnesses (Jaspers, 1999: 45–47, 55–60). One either becomes apolitical or one becomes blindly obedient; but all have lost the sense of value and worth (Jaspers, 1999: 73, 83). Whereas science once commanded respect, modern technology offers only manipulation. While philosophy had once promised understanding of humans, modern sociology now provides some comprehension of individuals and their interrelations (Jaspers, 1999: 128–130, 141). This answer hints at Jaspers' belief in an answer to the 'radical crisis.' But, it is not Marxism, psychology, or racial theory – it is Jaspers' own "philosophy of existence" (Jaspers, 1999: 146–148). Jaspers acknowledges his philosophical indebtedness to Nietzsche with the phrases like "becoming who we are" and 'self-becoming' (Jaspers, 1999: 152, 166). But, his method for overcoming alienation is his own; it is reseeing the world in a new light and rediscovering true friendship (Jaspers, 1999: 171, 177). One cannot escape the modern situation by moving away from oneself; instead, one must learn to live with oneself. Jaspers' answer to the problem of alienation in the modern world is to take up the task to "remember what it is to be human" (Jaspers, 1999: 183, 194).

The picture that Hannah Arendt painted of human beings and the human condition is often one of totalitarianism and terror. In works such as *The Origins of Totalitarianism*, *Eichmann in Jerusalem*, and in *Past and Future*, Arendt spelled out in great detail the failings of humankind. These all lead to a type of 'world alienation' in which we are cut off from our past and have no firm standards from which to judge. Arendt often wrote on the pressing topics of the day: the trial of Adolf Eichmann, the Vietnam War, and Watergate. But, like her mentor Jaspers, she looked to the great thinkers of the past, not in order to copy their thoughts and beliefs, but to see how they could provide a foundation for our own thinking and judgments. She understood that people tended to seek refuge from painful reality, but she was convinced that we have the obligation to ourselves and to others to confront the facts. In one of her last lectures she said: "When the facts come home to roost, let us try to make them welcome. Let us try not to escape into some utopias – images, theories, or sheer folly." (Arendt, 2003: 275). She may very well had Marx in mind when she wrote that; while she regarded him highly as a thinker who broke with tradition, she rejected his promotion of what she believed to be self-illusions (Arendt, 1968: 24, 28–30). We may be alienated from the world and from our labor, but the most personal form of alienation is the intentional alienation from ourselves.

Conclusion

This account of alienation was necessarily a selective one. There are some scholars who believe that forms of alienation are found in ancient and medieval times, but most agree that it is a modern phenomenon. There are many factors for this, but they would include the increasing rationality and decreasing religious beliefs. They would also include the increase in urbanization and most certainly the massive technological advances. These and other factors undoubtedly help human beings in many physical ways, but there is also no question that they increase the sense of distance from our 'natural' selves. With technical progress comes human alienation.

This account has focused almost exclusively on the conception of alienation; but the theme of alienation is also found in theology (Eric Fromm, Paul Tillich), psychology (Karen Horney, Franz Fanon), and existential literature (Albert Camus, Jean-Paul Sartre). Marx gave us his conception of alienation more than 150 years ago, but it still serves as one of the most definitive and compelling accounts of alienation in the modern age. Alienation can be regarded as "the plight of modern man" (Schacht, 1970: 1).

This article is a revision of the previous edition article by O.R. Holsti, volume 1, pp. 397–401, © 2001, Elsevier Ltd.

Abstract

Alliances are formal agreements, open or secret, between two or more nations to collaborate on national security issues. This article addresses several enduring concerns about alliances, including alliance formation, performance and persistence, international and national effects, and their prospects in the new millennium.

Prominent explanations for alliance formation include realist balance-of-power theories and game-theoretical theses postulating that alliances will increase only to the point of a minimum winning coalition. Still other theories look into various characteristics of members. The article then focuses on alliance performance and the various attributes associated with effectiveness or ineffectiveness, including purposes, similarities of members, size, alliance leadership, and the advent of nuclear weapons. The article then reviews a number of studies on the international and national impact of alliances. Although the 'age of alliances' – the third quarter of the twentieth century – has passed, there is strong reason to believe that alliances will continue to be among the more important instruments of statecraft.

Alliances are formal agreements, open or secret, between two or more nations to collaborate on national security issues. They have been variously considered as techniques of statecraft, international organizations, or regulating mechanisms in the balance of power. This article addresses several of the enduring concerns about alliances, including alliance formation; their performance and persistence; their effects on the international system and domestic politics; and their prospects in the new millennium.

Alliance Formation

Among the oldest explanations of alliances are those derived from balance-of-power theories in which the emphasis is on the external environment, including the structure, distribution of power, and state of relations between units of the system. These are often closely linked to the 'realist' approach to international politics (Morgenthau, 1959; Waltz, 1979; Gilpin, 1981). Balance-of-power politics are almost unthinkable in the absence of alliances. According to Morgenthau, "The historically most important manifestation of the balance of power, however, is to be found not in the equilibrium of two isolated nations but in the relations between one nation or alliance of nations and another alliance" (Morgenthau, 1974: p. 188). Nations join forces as a matter of expediency in order to aggregate sufficient capabilities to achieve certain foreign policy goals, to create a geographically advantageous position – for example, to create buffers or isolate a potential adversary – or to prevent any nation of combination of countries from achieving a dominant position. Alliance partners are thus chosen on the basis of common goals and needs, not for reasons of shared values, shared institutions, or a sense of community. According to balance-of-power theories, nations should be more likely to join the weaker alliance to prevent formation of a hegemonic one ('balancing') rather than to join the dominant one in order to increase the probability of being on the winning side ('bandwagoning') (Waltz, 1979). Several case studies found support for the 'balancing' hypothesis: that nations form alliances to balance threats rather than power (Walt, 1987). But permanent alliances are themselves detrimental to the system and must therefore be avoided. As Nicholas Spykman (1942: pp. 103–104) noted: "He who plays the balance of power can have no permanent friends. His devotion can be to no specific state but only to balanced power. The ally of today is the enemy of tomorrow. One of the charms of power politics is that it offers no opportunity to grow weary of one's friends."

Balance-of-power formulations are a useful point of departure for understanding some of the motivations underlying alliance policies, at least for some periods or regions. But the number of deviant cases is sufficiently large to raise some serious doubts that these formulations can provide a general theory of alliances (Dawson and Rosecrance, 1966). Alliances may also play functions other than balancing power or threats. They can serve as instruments for binding, restraining, and managing relations with other members of the alliance (Schroeder, 1976; Osgood, 1968; Ikenberry, 2001). Although it is a considerable oversimplification, there is more than a grain of truth in Lord Ismay's observation that North Atlantic Treaty Organization (NATO) served three important functions: to keep the Americans in, to keep the Soviets out, and to keep the Germans down. It is hard to imagine that the French or other victims of Hitler's aggression would have accepted a rearmed Germany that was not firmly embedded within NATO.

The 'size principle,' according to which 'coalitions will increase in size only to the minimum point of subjective certainty of winning,' is drawn deductively from 'game theory' (Riker, 1962: pp. 32–33). Coalition theories share a number of characteristics with balance-of-power models. Both place heavy emphasis on calculation of advantage, adequate information, and rationality in alliance formation. They also tend to assume that national attributes other than power are of little importance in the calculations leading to alliance formation. But on one point they appear to differ: whereas an important goal of 'ideal' balance-of-power systems is to prevent the rise of a dominant nation or group of nations, the primary motivation in game approaches is to form just such a coalition, with enough partners to ensure victory but without any additional

ones who would claim a share of the spoils. Although intuitively appealing, a number of difficulties arise when this approach is applied to international politics. If war offers the prospect of winning territories or other divisible rewards, there are advantages to forming an alliance no larger than is necessary to gain victory, but even in redistribution alliances the territorial interests of partners must be complementary, permitting a noncompetitive division of rewards. Moreover, when an alliance is formed for purposes of defense or deterrence, success is measured by its ability to prevent conflict, not by the territorial or other gains derived from successful prosecution of a war; hence, bigger is better. Another potential difficulty is the demanding requirement that leaders be able to measure capabilities with sufficient precision to define a minimum winning coalition. While doing so may be relatively easy in a legislature or political party convention, it is far more difficult in the global arena. Any propensity to use 'worst case scenario' reasoning in foreign policy planning will likely result in a much larger alliance.

In contrast to the balance-of-power and minimum winning coalition theories are those that emphasize attributes other than national interest or power. These approaches do not deny that national interests or power calculations influence alliance formation, but they also assume that we cannot treat nations as undifferentiated units if we wish to understand either their propensity to use alliances as instruments of foreign policy – as opposed to such alternatives as neutrality – or in their choice of alliance partners (Holsti et al., 1973). The common denominator is a suspicion that foreign policy orientations reflect motives that draw upon many sources, some of which may be related to national attributes.

Political stability is sometimes associated with a propensity to join alliances, and instability has been seen as an impetus to go beyond nonalignment and pursue a policy of 'militant neutralism.' On the other hand, leaders faced with domestic instability may actively court allies in the hopes of gaining external support for a tottering regime. By utilitarian criteria, small, poor, or unstable nations are relatively unattractive alliance partners, but such nations have often been sought as allies, and they have even become the focal point of acute international conflicts and crises; twentieth-century examples include Bosnia (1908–09), Serbia (1914), Cuba (1961–62), and Vietnam (1965–73).

Given a propensity to seek allies, does the choice of partners reflect a discernible pattern of preferences? Affinity theories focus on the similarities among nations as an element in their propensity to align. The premise that nations are likely to prefer partners with whom they share common institutions, cultural and ideological values, or economic interests is intuitively appealing, and NATO can be cited as an example, but it has received limited support in studies of pre-1945 alliances (Russett, 1971; Holsti et al., 1973; Walt, 1987). The initial expansion of NATO following disintegration of the USSR did, however, give priority to three former members of the Warsaw Pact which had most effectively moved toward political and economic reform– Hungary, Poland, and the Czech Republic. These three countries had most effectively undertaken political and economic changes that moved them away from the Stalinist institutions of the Cold War era prior to the Soviet collapse.

Alliance Performance

British statesman Lord Palmerston once noted that nations have neither permanent enemies nor allies, only permanent interests. Although the longevity of most alliances can better be measured in years than decades or centuries, these observations do not explain why some alliances are cohesive and effective whereas others are not. The alliance concluded between Great Britain and Portugal in 1703 has survived owing to a shared interest in naval security concerns in the waters around the two countries. In contrast, the 1955 Central Treaty Organization (CENTO) linking Great Britain, Iran, Iraq, Pakistan, Turkey, and, later, the United States was never very effective. It was called the Baghdad Pact until Iraq's withdrawal in 1959, and it died two decades later when Iran withdrew following the revolution that overthrew the Shah's regime. A range of theories has been advanced to explain alliance performance and longevity: some emphasize the attributes of the member nations; some the character of the alliance itself; and others the nature of the international system.

The relative merits of open (democratic) and closed (authoritarian) polities have often been debated, but without consensus. To some, open polities are inferior allies on two counts: they experience more frequent changes in ruling elites, with the consequence that commitments to allies may also change, and the demands of domestic politics may take precedence over alliance requirement. But when democracies are under attack they are more likely to expand alliance functions and to turn alliances into communities of friendship; they are also less likely to renege on commitment by seeking a separate peace (Liska, 1962: pp. 50, 52, 115). Machiavelli noted almost five centuries ago, "Alliances are broken from consideration of interest; and in this respect republics are much more careful in the observance of treaties than princes" (Machiavelli, 1950: p. 268).

Political instability is often associated with poor alliance performance. Unstable regimes may experience radical changes in elites, which in turn result in shifting patterns of alignment, and they may also be more willing to run high risks on behalf of their own interests but not those of allies. A classic example is Austria–Hungary in 1914. Fearing that the multinational Dual Monarchy would be torn apart by demands for autonomy from various national groups, Vienna pursued a punitive policy toward Serbia, initially with the full support of Germany, but later with little attention to advice emanating from Berlin. Some of the most dramatic cases of realignment or alliance defection, however, have occurred in nations with well-entrenched elites. Nazi–Soviet relations offer numerous illustrations. The Nazi–Soviet Pact of 1939 was inconsistent with the Franco-Soviet alliance of 1935 and the Anti-Comintern Pact, of which Germany was a leading member. In the ultimate act of perfidy, Hitler unleashed Operation Barbarossa against his erstwhile Soviet ally in June 1941.

Differences in national bureaucratic structures and processes may be an important barrier to coordination of alliance strategies. If national security policy is the product of constant intramural conflict within complex and varied bureaucracies, even close allies may fail to perceive accurately the nuances in the bureaucratic politics 'game' as it is played abroad, and how the demands of various constituents may

shape and constrain alliance policies (Neustadt, 1970; Allison, 1971). Recognition that bureaucratic conflict may affect foreign policy choices may usefully supplement perspectives that regard alliance policies solely as a matter of rationality and calculation.

Alliances differ in many ways, including the circumstances under which their provisions become operative, the type of commitment, the degree of cooperation, geographic scope, ideology, size, structure, capabilities, and quality of leadership. The ANZUS Treaty (Australia, New Zealand, United States) called only on its members 'to meet the common danger in accordance with its constitutional processes' in case of an attack in the Pacific area on any one of them, and it had rather minimal bureaucratic apparatus. NATO, on the other hand, commits its members through Article V to joint military action in case of an attack on any one of them and, unlike the ANZUS Pact, it has an elaborate political and military infrastructure. Article V was invoked for the first time following the terrorist attacks on New York and Washington in September 2001.

Presumably all nations prefer to join alliances that offer them an effective role in determining goals, strategy, and tactics; a 'fair' share of the rewards without undue costs; and the maximum probability of success in achieving their goals. Redistribution alliance might be expected to achieve fewer successes and to break up more easily than those whose primary motives are deterrence and defense. Failure to achieve goals has a disintegrative effect and, other things being equal, it is easier for an alliance of deterrence to succeed because it is sufficient to deny the enemy a victory or to maintain the status quo. A redistribution alliance, on the other hand, must not only be able to avert defeat; it must also achieve victory if it is to be successful. The rewards of an offensive alliance can be shared noncompetitively only when the goals of each nation are limited and do not overlap with those of allies. In contrast, the more security an alliance of deterrence provides for one nation, the more secure are the others likely to feel. It remains to be seen whether an alliance such as NATO can survive the disintegration of the threat that gave rise to its existence. A leading 'realist' theorist famously declared that 'NATO's days are not numbered, but its years are' (Waltz, 1993: p. 76). Since then, however, NATO has not only expanded, but it has played an important role in Bosnia, Kosovo, Afghanistan, and other conflicts. Waltz pronounced validation for his prediction by the somewhat dubious assertion that NATO was no longer an alliance after its chief adversary collapsed, but had become 'a means of maintaining and lengthening America's grip on the foreign and military policies of European states' (Waltz, 2000: p. 20).

Ideology may play a role in sustaining or dissolving alliance bonds. Even those who minimize the importance of ideology in alliance formation tend to agree that a shared ideology may ensure that issues are defined similarly and facilitate intra-alliance communication. A common ideology may sustain alliances, but only as long as its tenets do not themselves become an issue. When they do, alliances in which doctrinal questions are highly salient are less likely to endure than those in which they are of marginal importance. Concrete alliance problems such as the level of military contributions can almost always be resolved by compromise, but it is a good deal more difficult for 'true believers' to split their differences on questions of 'fundamental truth.' Competing claims by Chinese and Soviet leaders about whose doctrines and policies more faithfully represented Marxist–Leninist ideology exacerbated some of their more concrete differences, including the legitimate boundaries in some contested areas between the two countries that had formed an alliance in February 1950.

Large alliances are usually less cohesive than small ones. The larger the alliance, the smaller the share of attention that nations can give to each ally, and as the size of the alliance increases, the number of relationships within the alliance rises even faster. When two nations ally, theirs is the only relationship; if three more nations join them, the number of two-way relationships jumps to 10; and when NATO increased its membership from 16 to 28, the number of bilateral relationships jumped from 120 to 378. Problems of coordination increase and so do opportunities for dissension. Finally, the larger the alliance, the less important the contributions of any single member, and the easier it is for any partner to become a 'free rider' by failing to meet its alliance obligations.

Alliances differ widely in the kinds of political and administrative arrangements that govern their activities. Allies may undertake wide-ranging commitments to assist each other and yet fail to establish institutions and procedures for communication and policy coordination. This tended to characterize the alliance between Germany and Austria–Hungary during the years leading up to the First World War (Craig, 1965; Williamson, 1969). The Warsaw Pact may be used to illustrate the other extreme. Basic alliance decisions were made in Moscow, all key positions in the alliance were filled by Russians, and even discussions of defection were severely punished, as Hungary discovered in 1956. In contrast, France's partial withdrawal from NATO in 1966 provoked little response from its allies.

Some suggest that hierarchical and centralized alliances are likely to be more cohesive and effective because they can mobilize their resources better and respond more quickly to threats and opportunities. According to others, pluralistic and decentralized alliances are likely to enjoy greater solidarity and effectiveness. In pluralistic alliances, even differences on central concerns are likely to remain confined to the single issue rather than metastasize to all issues (Holsti et al., 1973).

The proposition that influence within an alliance is proportional to strength seems intuitively correct but it may not always be valid. Under some circumstances, weakness may actually be a source of strength in intra-alliance diplomacy. The stronger nation is usually the more enthusiastic partner, it has less to gain by bargaining hard, and it can less credibly threaten to reduce its contributions. The weaker nation may also enjoy disproportionate influence within an alliance because it can commit its stronger ally, which may be unable to accept losses resulting from the smaller partner's defeat (Olson and Zeckhauser, 1966).

Each state brings both assets and liabilities to the alliance. The conventional manner of assessing capabilities is to sum the assets of the members. The more realistic view is that the capabilities of an alliance rarely equal the sum of its parts. Given close coordination, similar equipment, skillful leadership, and complementary needs and resources, economies of scale may be achieved. This may sometimes be the case for alliances of deterrence, but if it becomes necessary to carry out

military operations, alliance capabilities are probably less than those of the individual nations combined. Wartime operations may reveal or exacerbate problems arising from poor staff coordination, mistrust, incompatible goals, logistical difficulties, dissimilar equipment, and organization. This is what Napoleon had in mind when he stated, "If I must make war, I prefer it to be against a coalition" (Padelford and Lincoln, 1967: p. 402), and the Duke of Wellington grumbled that having enemies is nothing like as bad as having allies. A century later Marshal Foch remarked, "My admiration for Napoleon has shrunk since I found out what a coalition was" (Rothstein, 1966: p. 125).

The capabilities of alliance leaders are of special importance. A powerful and wealthy bloc leader can offer side payments – private goods to supplement public ones – to smaller partners, which may in turn render the alliance more effective. According to the economic theory of 'collective action,' alliances that supplement public benefits (those that are shared by all members) with private or noncollective ones are more cohesive than alliances that provide only collective benefits (Olson and Zeckhauser, 1966). Except in pure conflict situations, there are always some tensions between the requisites of alliance cohesion and broader global concerns. If the alliance is to cope effectively with these tensions, it requires effective leadership from its leading member or members. Alliance relationships involve several kinds of tensions and fears. Members face fear of abandonment when their own interests are at stake, and of entrapment whose of others are threatened (Snyder, 1997). The ultimate test of alliance leadership comes during an international crisis when the leading partner may be forced to resolve serious tensions between alliance management (intra-alliance diplomacy) and crisis management (inter-alliance diplomacy).

This may entail a number of critical tasks:

- To convey to the adversary (1) evidence of a determination to maintain existing commitments; and (2) sufficient reassurance to reduce motivations for significant military escalation and, possibly, to permit bargaining on crisis issues.
- To convey to allies (1) assurances that their vital interests will not be sacrificed in seeking accommodation with the adversary (assuaging fears of abandonment); (2) assurances that they will not be drawn into a general war over issues of peripheral interest to the alliance as a whole (assuaging fears of entrapment); and (3) a resolve not to be drawn into a strategy of escalation on behalf of an ally which is willing to run unduly high risks in the pursuit of purely parochial interests.

Virtually every alliance faces the problem of ensuring the credibility of its commitments. The problem is most serious for alliances of deterrence. If adversaries possess serious doubts on this score, the alliance may serve as an invitation to attack. Equally important, if members have doubts about the assurances of their partners, the coalition is unlikely to be effective. 'Irrational' alliance commitments may be undertaken as part of an overall strategy of increasing the credibility of deterrence by conveying to the adversaries – and to other allies – that if the alliance leader is willing to expand vast resources to protect areas of little strategic values, then it should be clear that an even greater effort will be made to defend other allies (Maxwell, 1968: p. 8). Buttressing credibility by 'irrational' commitments may also entail risks – as the United States discovered in Vietnam – forcing the alliance leader to choose between unpalatable alternatives: reducing the commitment under threat, thereby seriously eroding one's credibility in the future; or backing the promise to the hilt, with the possibility of becoming a prisoner of the ally's policies.

Although it is widely asserted that alliance cohesion depends upon an external threat and it declines as the danger is reduced, this generalization must be qualified. Such threats may give rise to divisions if only part of the alliance membership feels threatened, if the threat strikes at the basis of alliance consensus, or if it offers a solution that sets off the interests of one ally against those of another. Occasionally, intense disputes may even break out between allies, as illustrated by the Cyprus issue between NATO members Turkey and Greece. Large alliances such as NATO are almost certain to experience circumstances that are perceived as a threat by only one or two members. The Suez crisis of 1956, the Yom Kippur War of 1973, and the US invasion of Iraq in 2003 are good examples. In the latter case, the Blair government in London joined the United States, but important NATO allies such as France, Germany, and Canada refused to do, citing doubts about the evidence presented by the Bush administration – doubts that proved to be completely valid – regarding Iraq's alleged weapons of mass destruction and complicity in the 2001 terrorist attacks on Washington and New York. The Polish uprising in 1956, the offshore islands crisis of 1958, and the Sino-Indian border conflict of 1962 were situations in which Moscow and Beijing differed rather sharply on their estimates of the threat. But the consequences of such divisive events were quite different for NATO and the Sino-Soviet alliance. Similarly, unless the external danger creates an equitable division of labor among alliance members, cohesion and effectiveness are likely to suffer. Although wartime alliances face considerable external threat, they may sometimes experience tensions because military operations rarely result in equal burdens. As long as the threat calls for a cooperative solution, cohesion will probably be enhanced, but should a solution that favors one ally at the expense of others appear, the alliance may lose unity or disintegrate. Finally, an alliance confronting an external threat for which there is no adequate response may also experience reduced cohesion or disintegration.

Expanding membership in the 'nuclear club' has generated an extensive debate on the likely consequences of nuclear weapons for alliances. Most analysts stress their negative effects. One reason is that contemporary military technology has permitted some nations to gain preponderant power without external assistance. Another strand of the argument is that nuclear deterrence will be less credible if it takes the form of one alliance member providing a 'nuclear umbrella' – extended deterrence – for the others. Put in its starkest form the question is: what nation will risk its own annihilation by using its nuclear capabilities as a means of last resort to punish aggression against its allies? When justifying their acquisition of nuclear weapons, the French asked, "Would Washington commit suicide to save Paris?" The other side of the argument is the fear that one may unwittingly become a nuclear target as a result of an ally's quarrels. The latter point is illustrated by New Zealand's decision in 1986 to deny port facilities to ships

carrying nuclear weapons. As a result, New Zealand was excluded from the ANZUS mutual defense pact.

Another aspect of the problem focuses not only on the *existence* of nuclear weapons, but on their spread to junior alliance members. The view that nuclear proliferation will result in disintegration of coalitions appears grounded in a strictly utilitarian view of alliances. The opposing thesis seems to follow from the position that because other considerations may be important in the life of an alliance, sharing nuclear capabilities will add to the sense of equality and cooperation among allies. Advocates of the first position can point to the *de facto* defections of France and China from their alliances; it is not clear which came first, however, the decision to acquire an independent nuclear deterrent or strains between Paris and its NATO partners and between Moscow and Beijing. The latter viewpoint receives support from Great Britain's continued adherence to NATO after becoming the world's third nuclear power.

International Effects of Alliances

The foregoing discussion has been concerned solely with the causes and conditions of alliances and their performance. We now turn our attention to their *effects* on the international system and on the nations that join or shun them.

Alliances are intended to play a central role in maintaining the balance of power. They provide the primary means of deterring or defeating nations or coalitions that seek to destroy the existing balance by achieving a position of hegemony. Even advocates of balance-of-power diplomacy attach a number of important qualifications. Alliances among great powers contribute to instability if they are strong enough to destroy the existing balance, or if they reduce the number of nations that may act in the role of 'balancers,' which, according to the theory, are supposed to remain uncommitted until there is a threat to the balance.

Alliance critics assert that they merely breed counter-alliances, thereby leaving no nation more secure, while at the same time contributing to polarization and international tensions. For this reason, Quincy Wright (1965: p. 774) suggested that international stability is better served by efforts to break up dangerous coalitions rather than merely offsetting them with counter-alliances. A further criticism is that alliances are incompatible with collective security, which requires every nation automatically to assist the victim of aggression; alliance commitments can thus create a conflict of interest. It does not necessarily follow, however, that in the absence of alliances nations will develop an effective collective security system. Indeed, alliances may arise from disappointed hopes for collective security. Thus, elimination of alliances may be a necessary condition for collective security, but it is not sufficient. Critics of alliances also suggest that they act as conduits to spread conflict to regions previously free of it. They can point to historical instances in which alliances had this result, as can those who stress that alliances serve a deterrent function. But Liska (1962; see also Weitsman, 2004) has come to the conclusion that alliances neither cause nor prevent conflict, nor do they expand or limit it. Another set of studies of all alliances during the period between the end of the Napoleonic Wars and the outbreak of the Second World War incorporates two premises. First, the greater the number of independent units, the more peaceful the international system, because nations can concentrate less of their attention to any other country (Deutsch and Singer, 1962). Second, maximum freedom of interaction between nations enhances international stability because pressures on each country tend to be cross-cutting rather than reinforcing, with the result that bargaining rather than war is a more likely strategy to resolve differences. The Deutsch–Singer assumptions have an evident relationship to several prominent alliance theories. They are quite consistent with theories of integration which postulate that cooperative interaction on one issues tends to nurture cooperation in others. They are also related to classical balance-of-power theories, the central argument of both being that entangling commitments tend to reduce the freedom of action necessary to maintain system stability.

Results based on a system-level analysis of 118 alliances indicate that alliance formation and international conflict are positively correlated for the twentieth century, but the relationship for the nineteenth century is negative (Singer and Small, 1968; Bueno de Mesquita and Singer, 1973). In an analysis of 265 conflicts in the 1815–1965 period, Siverson and Tennefoss (1984) found that equality of power, supplemented by an alliance between a major power and weaker nations, tended to restrain the likelihood of escalation. Kegley and Raymond (1982) concluded that peace is best preserved when the structure of alliances is moderately flexible and when alliance commitments are considered binding. But in some cases the data have yielded contradictory conclusions. Whereas Zinnes (1967) found a positive correlation between the level of alliance commitment in the system and the outbreak of war, Ostrom and Houle (1978) came to the opposite conclusion. Moreover, we may not yet be in a position to rule out the possibility of a spurious correlation between alliances and war. That is, could alliance commitments and international conflict be the product of some common underlying factor?

Another strand of theory, not necessarily incompatible with either of the above, sees alliances as a possible step in the process of more enduring forms of integration. This view begins with the premise that effective cooperation among units in one sphere of endeavors gives rise to collaboration in others and, in the long run, to institutionalization of the arrangements. Presently available evidence appears to support those who doubt the integration potential of alliances. A study of 10 political communities in the North Atlantic area revealed that alliances were neither necessary nor sufficient for integration (Deutsch et al., 1957). A detailed study of NATO supports these findings. Not even in areas thought to be especially promising – armaments, infrastructure, and science – was there evidence of integration (Beer, 1969). Others have similarly concluded that cooperation in security-related matters has a lower potential for 'spillover' than collaboration in issue areas such as economic relations (Etzioni, 1962).

Finally, alliances may be related to change in the structure of the international system. For example, the more cohesive the alliances on matters of substance and strategy, the more polarized the international system. But propositions of this form are of fairly limited interest as they tend to be true by definition; that is, a polarized system is usually defined as one

in which alliances are cohesive and rigid. Thus, we are impelled to ask further questions, such as: under what circumstances are alliances in a balance-of-power or loose bipolar system likely to become rigid, thereby transforming the nature of the system?

National Effects of Alliances

Alliance benefits may include enhanced security, reduced defense expenditures, and possible side benefits such as economic aid and prestige. A strong ally may be a necessary condition for survival. But alliances may be a net drain on national resources, they may distort calculations of the national interest if allies become wedded to 'inherent good faith' models of each other, and they may lead to the loss of decision-making independence. And, if alliances merely trigger off counter-alliances, they may leave everyone poorer and less secure.

Prospects

The third quarter of the twentieth century – 'the age of alliances' – was ushered in by the formation of NATO in 1949 and the Sino-Soviet Security Treaty in 1950. Within a decade the Warsaw Pact, Southeast Asia Treaty Organization, CENTO, and a multitude of other bilateral and multilateral alliances were formed, but many of them dissolved before the end of the Cold War. Contrary to the expectations of some 'realist' theorists, however, NATO has outlived the threat that brought it into existence. Although many Cold War alliances failed to survive into the new millennium, as long as the international system is characterized by independent political units, alliances are likely to persist as a major instrument of statecraft. According to Snyder (1997: p. 78), alliance formation is "the product of systemic anarchy, strength inequalities, and conflict and common interests among states." Because those conditions are likely to characterize the global system as far as one can foretell, alliances are likely to remain among the most important means by which states pursue their interests.

Abstract

Gordon Allport, a major American psychologist of the mid-twentieth century, made significant contributions to both personality and social psychology. His 1937 book, *Personality*, helped to establish personality as an essential component of academic psychology. His 1954 book, *The Nature of Prejudice*, became a classic in social psychology and shaped the study of intergroup relations for half a century. In both areas, Allport's work is characterized by three interwoven features: a broad, eclectic balance of the many sides of psychology; the specification of central problems with initial approaches to their solution; and a uniquely consistent, seamless, and forceful perspective.

Gordon Willard Allport was a major American personality theorist and social psychologist of the mid-twentieth century. His legacy in psychology is twofold. He helped to establish personality psychology as a science and as an integral part of the discipline of academic psychology. In addition, his applied work in social psychology, particularly on intergroup prejudice, furthered the practical value of the discipline's work on important social problems.

The son of a Scottish American medical doctor, Allport was born on 11 November 1897 in Montezuma, Indiana, USA, and grew up in Cleveland, Ohio. His early life strongly shaped his later ideals and achievements (Elms, 1993; Nicholson, 2003). Allport's half-century affiliation with Harvard University began in 1915 when he enrolled as an undergraduate. His student career foretold his adult interests in science and social issues. He majored in both psychology and social ethics and was impressed by his first teacher in psychology, Hugo Münsterberg. He spent much of his spare time in social service activities. This convergence of interests took institutional form later, when he helped to establish both the Society for the Psychological Study of Social Issues and Harvard's Department of Social Relations.

Upon graduation in 1919, Allport taught English and Sociology at Robert College in Constantinople (then part of Greece, now Bogazici University in Istanbul, Turkey). In addition to German, he remained fluent in Modern Greek throughout his life. Returning to Harvard in 1920, he completed his PhD in psychology in 2 years. His dissertation title again reflected his dual commitment to science and social concerns: An Experimental Study of the Traits of Personality: With Special Reference to the Problem of Social Diagnosis. In addition, he assisted his older brother, Floyd, in editing the *Journal of Abnormal and Social Psychology*, the start of more than four decades of association with this core publication of the discipline.

Harvard then awarded him a coveted 2-year Sheldon Traveling Fellowship. He spent the first year in Germany, where the new *Gestalt* school and its emphasis on cognition fascinated him. Indeed, he became a partial Gestaltist – partial because he could not accept the Gestaltists' assumptions about the inflexible genetic basis of cognitive processes (Pettigrew, 1979). He spent his second Sheldon year at Cambridge University, where the experimental psychologists coolly received his report on *Gestalt* developments.

In 1924, Allport became a Harvard instructor in social ethics and taught what was probably the first personality course offered by a North American university. Two years later he temporarily severed his connection with Harvard to accept an assistant professorship in psychology at Dartmouth College. Yet, even during his brief 4 years away, he returned repeatedly to teach in Harvard's summer school. In 1930 he came back to Harvard to stay.

Allport's unique contributions to psychology are best described by three interwoven features of his work. First, he offered a broadly eclectic balance of the many sides of the discipline – holding to William James's contention that there were "multiple avenues to the truth." Second, he formulated the central future explanatory problems of the discipline and proposed original approaches to them. Finally, his entire body of scholarly work presents a consistent, seamless, and forceful perspective.

Broadly Eclectic Balance

Allport sought an eclectic balance for both methods and theory. His two most famous volumes on personality illustrate this dominant feature of his work (Allport, 1937, 1962; Pettigrew, 1990). He urged, for example, the use of both ideographic (individual) and nomothetic (universal) methods. Since he thought the discipline relied too heavily on nomothetic approaches, he sought greater use of ideographic techniques. In an age of indirection, Allport insisted that if you want to know something about a person, why not first ask him? Considered scandalously naive at first, his position helped to right the balance in assessment.

Typically, his was an expansionist, not an exclusionist, view. He simply sought a reasonable trade-off between accuracy and adequacy. Allport thought the two foci together would make for 'a broadened psychology.' Indeed, his own empirical efforts ranged from personal documents, such as *Letters from Jenny* (Allport, 1965), to two popular tests on ascendance-submission and personal values. He also developed ingenious experimental procedures to study eidetic imagery, expressive movement, radio effects, rumor, the trapezoidal window illusion, and binocular rivalry.

His theoretical efforts also sought a balance. He vigorously advocated an open system theory of personality with emphases on individuality, proaction, consciousness, maturity, and the unity of personality. As such, in Rosenzweig's (1970: p. 60) view, Allport served as the field's 'ego' in contrast to Henry

Murray's 'id' and Edwin Boring's 'superego.' Yet Allport did not hold his emphases to be the only matters of importance for a psychology of personality. Rather, it was because he believed the discipline was granting ego concerns too little attention.

In this sense, Allport was, to borrow from boxing, a counterpuncher. He opposed what he regarded as excessive trends in psychology that threatened his conception of an open, balanced discipline. In 1937, in his first personality book, he saw as the major threat the too-rigid applications of experimental psychology. By 1961, in his second personality volume, he saw as the major threat the too-loose applications of psychoanalysis. "Although much of my writing is polemic in tone," he confessed in his autobiography, "I know in my bones that my opponents are partly right." The key word is *partly*. Allport opposed excess, "the strong aura of arrogance found in … fashionable dogmas" (Allport, 1968: pp. 405–406). So he held fast to the open middle ground as he perceived it, and aimed his punches at the 'fashionable dogmas' that existed in each period. Modern readers may miss the significance of his arguments if they are unaware of which dragons he is attempting to slay.

Formulating Central Explanatory Problems and Offering Original Solutions

Psychology recognized Allport throughout his career as a source for specifying the discipline's central problems with explaining behavior. Typically his initially proposed solutions to the problems – such as functional autonomy – won limited acceptance. Nonetheless, many of Allport's initial proposals for addressing basic problems now exist in psychology with new labels and enlarged meanings. Allport only loosely sketched out his innovative ideas. Later work accepted the problem and expanded the ideas. Consider the much derided concept of functional autonomy. The notion that motives can become independent of their origins was considered heretical in 1937. Slowly, psychology came to accept the phenomenon if not the formulation. Today, social psychologists reconceptualize the process in interactionist terms. Motives, established and functional in one situation, lead individuals to new situations where the same motives persist but assume new functions.

Similarly, Allport's conception of personality traits has often been criticized. What critics attack is the mistaken notion that he held a static view of traits as pervasive, cross-situational consistencies in behavior. But Allport advanced a far more dynamic conception of traits. In fact, he was "an interactionist in the sense that he recognized behavior is determined by the person and situation" (Zuroff, 1986: p. 993).

Indeed, Allport broke early ground for many ideas that are now fully developed and accepted. Thus, he provided in his 1937 volume a social constructionist interpretation of identity. And his insistence on multiple indicators and methods offered an initial statement of Campbell and Fiske's (1959) multitrait–multimethod approach.

A Consistent, Forceful Perspective

Above all, Allport's contributions to psychology flowed from a consistent and forceful perspective presented in graceful prose. One reviewer of his 1937 *Personality* book wrote, "One has all the way through it a distinct feeling that 'This is Allport'" (Hollingworth, 1938: p. 103). This pointed observation holds true for all his writing.

Allport's perspective remained consistent but not static throughout his career. He acquired a comprehensive knowledge of the psychological literature from his long years as a meticulous editor. Quite literally, a large proportion of North America's personality and social psychological literature in mid-century crossed his editor's desk. His mastery of the literature also reflected his open-ended view of theory – a view more Popperian than the strict Vienna circle positivism that held sway throughout most of his career.

Yet Allport held to his perspective forcefully. Blunt prose and forthright, critiques characterize his writing style. As one disgruntled reviewer of an Allport book put it, 'There is something in it to irritate almost everyone' (Adelson, 1956: p. 68). Hall and Lindzey (1957) suggest that Allport's many years of teaching led to his expressing his views in a uniquely salient and provocative style.

Allport on Prejudice

This directness is also apparent in his applied volume, *The Nature of Prejudice* (Allport, 1954). This influential book again brought together the combination of science with social action that Allport expressed early in his career. He deemed it his proudest achievement because he thought it "had done some good in the world." Indeed, in its paperback edition, it became one of the best selling social psychological books ever published.

The Nature of Prejudice displays the special characteristics of Allport's contributions to psychology. The volume offers a broad, eclectic perspective with a lens model that ranges from history to the psychological effects of prejudice on its victims. Its open view of the many sides of the phenomenon again demonstrates the distinctive quality of Allport's wide-ranging thought. This book is another seamless work that is 'Allportian' from start to finish. Deftly crafted in a simpler style than his other writings, Allport strove to make it accessible to a wider, nonacademic audience. In addition, it served to structure the entire study of prejudice for the next half a century. This is true for intergroup research in North America; and, in its many translated versions, it has also proven highly influential throughout the world. Its enormous impact is indicated by the existence of a volume with 44 diverse authors that marked the 50th anniversary of the publication of *The Nature of Prejudice* (Dovidio et al., 2005). Indeed, Allport's many predictions, though largely shaped by American intergroup data, have typically been confirmed in studies of intergroup prejudice throughout the world.

The Nature of Prejudice's useful definition of prejudice – "an antipathy based upon a faulty and inflexible generalization" (Allport 1954: p. 9) – stressed both affective and cognitive components, but it wisely left the complex link between prejudice and behavior an open, empirical question. This definition has served the field well, and only recently have social psychologists advanced expansions of its terms.

To attain his distinctive quality of balance, Allport again assumed the role of counterpuncher against prevailing dogmas.

He gave full recognition to the importance of the psychoanalytically inspired authoritarian personality syndrome, which he also had uncovered during the 1940s. But he challenged the Freudian formulation of aggression with a rival theory. Instead of the psychoanalytic steam boiler model of aggression and catharsis, Allport proposed a feedback model with dramatically different implications for prejudice and its remediation. Aggression, he argued, feeds on itself. That is, the acting out of aggression, rather than leading to less aggression, actually increases the probability that further aggression will be expressed. Armed with this insight, *The Nature of Prejudice* proceeds to advocate policies that have indeed reduced levels of prejudice throughout the world – including areas with long histories of intergroup conflict such as Northern Ireland and South Africa.

The book's most important theoretical contribution to addressing prejudice was the intergroup contact hypothesis. He argued that such contact was crucial for improving intergroup relations and that four conditions of the intergroup interaction were critical: equal status in the situation, common goals, no intergroup competition, and authority sanction. Extensive contact research throughout the world has supported his contentions; and these four conditions have proven to be important facilitating, though not essential, factors in reducing intergroup prejudice (Pettigrew and Tropp, 2011). His treatment of prejudice also countered the then-fashionable assumption that group stereotypes were simply the aberrant cognitive distortions of prejudiced people. Instead, Allport held that the cognitive components of prejudice were natural extensions of normal processes, a view now firmly established and universally accepted. Stereotypes and prejudgment, he concluded, were not aberrant at all but unfortunately all too human.

Allport's foresight into the many advances that prejudice research has achieved over recent decades, including in research on group stereotypes, can be traced to his early *Gestalt* training (Pettigrew, 1979). He devoted 10 of *The Nature of Prejudice*'s 31 chapters to cognitive factors and psychology joined the cognitive revolution just after the volume was published. In social psychology, social cognition veered in the largely *Gestalt* direction that had molded Allport's perspective on prejudice. Thus, the influences that shaped the study of prejudice in general and stereotypes in particular from 1960 on, were influences that had earlier guided Allport's thought.

The Nature of Prejudice also presents a host of original hypotheses on specific topics that have stood the test of time. For instance, one now popular theory of prejudice reduction emphasizes recategorization through identity with larger, more inclusive groups. Allport (1954) advocated the same mechanism. Drawing concentric circles with family in the center and humankind at the periphery, he argued that "concentric loyalties need not clash" and that prejudice is minimized by inclusive group membership.

The volume also devotes an entire chapter to the link between religion and prejudice. A devout Episcopalian, Allport was disturbed that research routinely finds nonbelievers far less prejudiced on average than members of organized religions. He proposed a critical distinction between an 'institutionalized' religious outlook and an 'interiorized' one. The more numerous institutionally religious, he argued, are the highly prejudiced. Those of the interiorized type, who have internalized their religious beliefs, are held to be far less prejudiced. In his last empirical publication (Allport and Ross, 1967), Allport presented evidence in support of his hypothesis.

Later work by Batson and his colleagues has extended this view (Batson and Stocks, 2005). They find that Allport's two types exist as independent dimensions of religiosity but not as polar opposites. Further, they add a third, independent religious orientation – 'quest' – in which people face directly such difficult religious issues as the meaning of life and personal mortality in all their complexity. And how these three types relate to prejudice is dependent on whether the prejudice is religiously proscribed or not and whether it is measured overtly or covertly. The institutionalized religious do indeed tend to be more prejudiced on both types of measures when the prejudice is proscribed. The interiorized religious, however, tend to be more prejudiced when the prejudice is not proscribed and is measured covertly. Only those with the quest orientation tend to be less prejudiced regardless of whether the prejudice is proscribed or not and how it is measured.

Allport addressed his prejudice volume primarily to his own in-group – White, Protestant, American males. The examples of prejudice cited throughout involve anti-Black, anti-Jewish, anti-Catholic, and antifemale sentiments. He was clearly lecturing to 'his own kind.' It is safe, easy, and politically expedient to attack the prejudices of out-groups who hold negative views of your in-group. It is quite a different matter to attack the prejudices of your own in-group toward others. So yet another remarkable feature of *The Nature of Prejudice* is its target audience.

Allport as Teacher and Mentor

Though intellectually confident, Allport was a shy and modest man – though his manner was sometimes mistaken for aloofness. In his gentle and supportive way, he was a master teacher and mentor. Consistent with his conception of the uniqueness of personality, he encouraged students to follow their own interests. Hence, though he produced dozens of well-known psychologists, he never developed a 'school' of followers.

One way Allport handled his social shyness was to prepare carefully for occasions in advance. Before giving his Hoernle Lecture at South Africa's leading Afrikaner University at Stellenbosch in 1956, he studied Afrikaans with a tutor for 6 months. He then skillfully gave the introduction to his lecture in Afrikaans, gracefully apologizing for not delivering his entire address in Afrikaans. The Afrikaner audience, accustomed to even other South Africans not knowing their language, reacted with surprise and delight. The audience arose as one with applause.

The Lasting Contribution

The forcefulness and integrity of his work can be seen in Allport's many professional honors. He was elected president of both the American Psychological Association (1939) and the Society for the Psychological Study of Social Issues (1944). He

received the Gold Medal of the American Psychological Foundation in 1963, a few years prior to his death on 9 October 1967 in Cambridge, Massachusetts. The eclectic nature of his work, along with his essential contributions to psychological explanation, is apparent in his legacy to both modern personality and social psychology. Specialists in personality have expanded his conception of traits and now use the concept as a major tool (e.g., Lilienfeld, 2005; Piekkola, 2011). They also draw on Allport's writings to support a resurgence of interest in the uniqueness of individuals (Barenbaum, 2005; Lamiell, 2009). Social psychologists constantly cite his classic on prejudice. Indeed, according to the counts of Google Scholar, Allport's the *Nature of Prejudice* is cited twice as often as his two popular personality texts.

Alternative Food Movements

Liz Grauerholz and Nicole Owens, University of Central Florida, Orlando, FL, USA

Abstract

We review several alternative food movements (AFMs) that have emerged in response to changing food production during the twentieth century. The shift from small-scale, family-owned operations to massive, corporatized factories has resulted in concerns about human health, environmental degradation, and animal welfare; and it is around these issues that AFMs have emerged. The rise in AFMs seems to signal a growing desire for more personal connections between consumers and producers, and between producers and their products. Here, we discuss some of the established AFMs as well as newly emerging ones.

Introduction

New social movements surrounding food systems, especially the production of food products and their consumption, have grown dramatically over the past several decades. These movements emerged primarily as a response to a food production system that has become increasingly industrialized, standardized, and impersonal since the mid-twentieth century, when food production shifted from mostly small-scale, family-owned operations to large, corporatized farm factories, motivated by the same profit principles found in any other type of business. Outputs dramatically increased with these shifts but so did some disturbing outcomes (Lyson, 2004). As a result, concerns about the health – of humans, other animals, and the environment – as well as the ethics and risks of contemporary food production practices have been raised. It is around these issues that alternative food movements (AFMs) have emerged over the past 30–40 years.

Background

Since the mid-twentieth century, farming has transitioned from family-owned, diversified, and independent farms that raise a variety of crops and a few animals to farm factories that produce one crop or animal in intensive, confined space and are owned by a few corporations rather than families (Pew Commission on Industrial Animal Farm Production, 2009). This change in food production systems was prompted primarily by the 'Green Revolution' during the 1940s–1960s that relied on "a regime of genetic selection, irrigation, and chemical fertilizers and pesticides" (Pew Commission on Industrial Animal Farm Production, 2009: p. 3). The Green Revolution resulted in substantial increases in agricultural productivity. Crop yields doubled or tripled between 1940 and 1980. Similarly, meat, milk, and egg production increased dramatically, thanks in part to the low cost of feed grain, genetic selection, and chemical additives to feed (Pew Commission on Industrial Animal Farm Production, 2009).

During the latter part of the twentieth century, agriculture was further transformed by the 'Biotechnology Revolution,' as genetically modified (GM) plants and animals were introduced, allowing producers to breed for specific qualities in plants and animals (Lyson, 2004). Both the Green Revolution and Biotechnology Revolution promised and succeeded in generating greater output of animals and plants at lower costs, which has been a boon for many food producers as well as consumers around the world who need affordable food.

AFMs have emerged in large part in response to the Green Revolution and to a lesser but significant extent, the Biotechnology Revolution. The current popularity of farmers' markets (FMs), inner-city markets, community supported agriculture (CSA), resistance to mass-produced and biotech foods, and so on, signal a return of food production and marketing practices common prior to the Green Revolution. Until the emergence of large retail chain grocery stores (supermarkets) in the early twentieth century, both urban and rural dwellers often produced their own food and bought or bartered the rest from local farmers and specialized vendors (e.g., butchers). What characterized these food markets or practices, or direct agricultural markets, were face-to-face interactions between consumers and producers (farmers) (Hinrichs, 2000). With the emergence of technological advances in farming, chain groceries, and urbanization, these direct agricultural markets and practices were pushed to the margins, severing the personal connection between producers and consumers. In almost all cases, the rise in AFMs signals a return to more personal connections between consumers and producers and between producers and their products.

The Local Food Movement

The local food movement privileges local, seasonal foods over exotic, durable ones (Hinrichs, 2000). Although 'local food' has many meanings, these basic principles have had a major impact on contemporary food movements. They have forged new connections between producers and consumers and those between individuals and the land, and have reshaped the social, economic, and physical landscapes of thousands of communities. Lyson (2004: p. 1) calls the local food movement 'civic agriculture', drawing attention to the tight link between these farming practices and a community's social and economic development.

The local food movement has multiple origins but one of the most important is environmental. Over the past 50 years, food from around the world has become widely available throughout the year – bottled water from Fiji, apples from Chili

in springtime, watermelons from China in winter – are featured in virtually any grocery stores catering to middle- and upper-class shoppers. As a consequence, food may travel hundreds or thousands of miles from field to plate, requiring enormous amounts of nonrenewable resources to process, package, and transport, making food production and marketing two of the most environmentally unfriendly businesses in the world. Here, we discuss the major players in the local food movement – FMs and CSAs – as well as more recent trends that have taken on a do-it-yourself quality that includes urban farming and gardening.

FMs emerged as a major player in the contemporary local food movement in the 1970s. In the USA, there were 1755 FMs in 1994; that number increased to 8144 in 2013 (USDA, 2002, 2013b). FMs are found worldwide; some of the largest operate in Japan and Australia. These FMs are supported by consumers who desire greater freshness and quality of products than typically found in stores, hold idealized images of 'local farmers' and less conventional agricultural practices, and who want to help local economies and farmers and feel more connected to their communities (Ostrom, 2006; Smithers et al., 2008).

In theory, FMs involve producers who "sell directly to retail customers … selling legal goods produced by small scale firms outside of the mass distribution system" (Tiemann, 2004: p. 54). But as the popularity of FMs has grown, so too has their diversity. There exist 'indigenous markets' that operate with no formal rules yet adhere to selling only local, seasonal product, as well as 'experience markets' governed by written, formal rules (Tiemann, 2004). In British Columbia, for example, 'make-bake-grow' restrictions at many markets prohibit resale of items (Wittman et al., 2012). FMs may vary from just a few vendors to massive markets that no longer resemble what most think of as an FM. For example, the Los Angeles' Original Farmers Market began in 1934 with 18 farmers and merchants who paid 50 cents a day to park their trucks on vacant land to sell their products to local shoppers; today it offers not only local products but chain restaurants, gourmet groceries, and even online shopping.

FMs are likely to continue to grow because they benefit all parties. It is less costly for farmers to sell directly to consumers, and the reduction of transportation, storage, and processing costs and time means that consumers have access to fresher, healthier foods, usually at lower costs than found in grocery stores. Unquestionably, part of the popularity of FMs stems from their ability to bring communities together and create distinctive cultures, especially for those who feel that urban areas have become too impersonal and commercialized.

Another component of the local food movement is CSA. Although there is wide variability in how CSAs operate, typically consumers purchase an initial membership or subscription and in return, receive a 'share' of the farmer's bounty – seasonable yield – throughout the growing season. What makes CSA unique is the concept of 'shared risk.' Consumers shoulder some of the burden typically carried by farmers alone. In a good year, when yield is plentiful, consumers may get more lettuce and rhubarb than expected (or desired). In other years, if crops are destroyed by disease, disaster, or weather, consumers may get very little in return for their investment.

CSAs can be traced back to community-based farming systems in Japan and Switzerland during the 1960s and 1970s. In 1965, a group of Japanese mothers created the first CSAs, or 'Teikei' (Fairshare CSA Coalition, 2013). In the USA, the first two CSAs began in 1986 but quickly spread. The USDA reported that 12 549 farms marketed their products through a CSA in 2007 (USDA, 2007). According to the Rodale Institute (2013), CSA exists in Australia, Hungry, India, Hong Kong, France, Denmark, Holland, Germany, England, Brazil, Argentina, and Venezuela. In Japan, the Teikei movement is still thriving.

In addition to promoting deeper ties between farmers and consumers, CSAs often provide important benefits to the wider local community. In a survey of CSA farms (Center for Integrated Agricultural Systems, 2013), nearly three out of every four farms held social and educational events for members and the nonmembers, and more than half provided programs for low-income families and donated unclaimed food-to-food banks.

Urban gardening, which has existed since the 1890s and was especially popular during economic depressions and wartime (Lawson, 2005), has resurfaced as one of the more recent trends within the local food movement. While both FMs and CSAs center on the connection between farmer and consumer, urban gardening eliminates the 'middleman' altogether and turns consumers into producers. These include backyard and community gardens, and even small-scale farming of animals.

According to Lawson (2005), neighborhood community gardens are the most common type of urban gardening today. Typically, individuals sign up for a plot of land on which they grow anything from staples to feed their families to gourmet edibles not available in stores (Lawson, 2005). Community gardens have sprung up in large urban areas, slums, suburbs, and small villages and towns. Several countries, including China, Japan, and Cuba, have well-established, successful community gardening programs (e.g., Havana, Cuba has nearly 200 city farms) (Shaikh, 2013). On the other side of the world in a Kenyan slum where land and food is scarce, residents are learning how to grow food in large bags of compost (Shaikh, 2013).

Two more recent trends in urban farming and gardening are worth noting. The edible frontyard has generated considerable attention in recent years in the US. Though 'edible landscaping' has been popular for years and common in many parts of the world, these frontyard gardens typically replace entire lawn with garden beds, a practice guaranteed to offend some neighbors and city officials. In fact, frontyard gardeners have been ordered to remove their gardens or risk fines and jail (Kurutz, 2012).

Perhaps even more controversial is the recent trend in urban chicken keeping, a practice that is gaining greater acceptance in the USA. According to a USDA (2013c) survey, about 44% of those surveyed were accepting of chickens in their communities, 39% said they would not object to their neighbors raising chickens, and 4% of households planned to have chickens. Interestingly, chicken keeping has been found to restructure the family division of labor in some parts of the world by bringing children and women back into family production. In Botswana, for example, where women have assumed the lead in raising chicken for food and profit, their status has increased as

they come to be viewed as independent, productive, and entrepreneurial (Hovorka, 2012).

The local food movement has clearly become part of the food system and is likely to continue to do so, especially since it overlaps with consumers' desire for healthier, plant-based, organic products. Whether the newer manifestations of the local food movement such as backyard chicken coops and frontyard gardens survive remains to be seen and may well depend on the ability of movement activists and gardeners to frame these practices in terms of broader social issues such as children's and families' health and sustainability. But there are other challenges to the local food movement. Local farming and gardening are seasonal activities and the types of produce grown are limited. Today's consumers have come to expect and appreciate the diversity and availability of nonlocally grown foods, and few families today have the time or skill to preserve foods. It is unlikely that families can survive on local yield alone, thus local foods are likely to supplement rather than replace conventional food production and consumption.

Plant-Based Diets

Individuals who transition or convert to plant-based diets usually cite concerns about health, animal welfare, and the environment (Beardsworth and Keil, 1992). Although individuals may see these concerns as distinct, in reality they are closely related – largely stemming from the mass production of animals as food that have characterized meat production in the US and to a lesser extent, around the world, for several decades.

Although the percentages of individuals who consider themselves to be vegetarian and vegans are relatively small (5 and 2%, respectively; Gallup, 2012), many more individuals claim to incorporate plant-based foods in a deliberate way. According to one study, 40% say that when they eat out they often order a vegetarian dish, and 16% say that more than half their meals are vegetarian (The Vegetarian Resource Group, 2011). An NPR (National Public Radio)-Truven Health Analytics Health Poll (2013) also found that 39% of those surveyed said they eat less meat than they did even 3 years ago. In the spirit of supply and demand, plant-based options are more and more likely to appear on restaurant menus; Rowe (2013) cites an 11% increase in a 3-year period. The use of 'meat alternatives' (faux-meats) is increasing and vegan foods (i.e., containing 'no animal ingredients') saw the biggest gains (200%) in new products marketed between 2008 and 2012 (Food Product Design, 2013).

Although the rates of vegetarianism have not been well documented over time (compounded by the fact that there are no shared definitions of 'vegetarian' among those practicing it), these numbers almost certainly reflect a growing awareness of the benefits of adopting more plants into one's diet. Indeed, public messages promoting plant-based diets have intensified and stem from multiple sources – for example, animal rights activists and health advocates – thereby reaching more individuals and gaining momentum.

If a social movement's impact can be measured by how well its message has been incorporated into mainstream culture, the plant-based diet movement has been highly successful. For instance, the Academy of Nutrition and Dietetics, the world's largest organization of nutrition and food professionals, states that vegetarian diets have a wide range of health benefits including reduced risk of heart disease, cholesterol levels, blood pressure, hypertension, diabetes, obesity, and cancer. The 'Meatless Mondays' campaign is associated with prestigious universities including Johns Hopkins, Columbia, and Syracuse, and it works with schools, universities, government organizations, businesses, hospitals, and media around the world. According to Barclay (2013) about 43% of Americans were aware of the Meatless Monday campaign and of those, 36% said it caused them to reduce meat consumption or consider doing so. Its impact is not just felt in the United States; their Web site boasts that 29 countries have active Meatless Monday programs.

In addition to health issues, concerns about animal treatment and environmental degradation associated with current farming practices have also spurred interest in plant-based diets. These concerns stem mostly from the practice of producing animals in Concentrated animal feeding operations (CAFOs). CAFOs are a type of Animal Feeding Operation distinguished by the number of animals, conditions of confinement, and waste management utilized. These facilities "congregate animals, feed, manure and urine, dead animals, and production operations on a small land area" (EPA, 2012). Although CAFOs produce inexpensive food in greater abundance, the high concentration of animals in industrialized facilities has resulted in serious health concerns, environmental degradation, and animal mistreatment.

The most critical health issue stems from the amount of manure CAFOs produce (Hribar and Schultz, 2010). Although manure in small quantities is beneficial to farms, the quantities produced by CAFOs far exceed manageable levels. The Environmental Protection Agency (EPA) acknowledges that livestock animals in the US produce about 1.2–1.37 billion tons of waste every year – far more than that produced by humans. For example, a single facility with 800 000 pigs produces about 1.6 million tons of waste annually – more than one and a half times that produced by the city of Philadelphia, Pennsylvania (Hribar and Schultz, 2010). Unlike human waste, livestock waste is not treated or well contained (Hribar and Schultz, 2010), posing serious health hazards. Animal manure contains more than 150 pathogens that potentially affect human health, including nitrates and *Escherichia coli*, which can leach into the ground and surface water (Hribar and Schultz, 2010). CAFOs also affect air quality, as they produce high levels of "ammonia, hydrogen sulfide, methane and particulate matter, all of which have varying human health risks," including respiratory problems and death (Hribar and Schultz, 2010: p. 5). In addition, the extensive use of antibiotics in animal feed contributes to antibiotic-resistant bacteria, and inbreeding for desirable traits reduces biological and genetic diversity that threatens food security (Pew Commission on Industrial Animal Farm Production, 2009).

Since the primary goal of CAFOs is profit, not animal welfare, it is no surprise that the treatment of animals at all stages of production – rearing, transport, and slaughter – has

raised ethical and moral concerns. Increased awareness of both routine treatment and conditions within CAFOs (e.g., inability of animals to exhibit natural behaviors, physical alteration of animals without pain relief, close confinement) and excessive cruelty and neglect of captive animals (often revealed by undercover investigations) have led consumers to demand changes in animal treatment. One study found that 75% of the public would like the US government to impose mandates for basic animal welfare measures (cited in Pew Commission on Industrial Animal Farm Production, 2009).

Individuals who adhere to plant-based diets may frame their choices differently. Some focus mostly on the consumption angle, focusing on their own health; others focus on the production angle, wishing to avoid practices that harm the environment and create animal suffering. They also do not necessarily share interests with those engaged in other AFMs. That is, vegetarians are not necessarily opposed to intensive farming practices of crops or GM crops. Despite these differences, collectively they have succeeded in raising public awareness that reduction or elimination of meat in favor of plants is beneficial to human health, the environment, and animals.

Genetically Modified Organisms: Emergence and Resistance

Genetically modified organisms (GMOs) refer to plants or animals whose genetic materials have been altered by adding, removing, or changing their DNA sequences in ways that are not naturally occurring (European Food Safety Authority, 2013). Commonly, GMOs involve the transfer of DNA from one species (e.g., bacteria, virus) into another in order to introduce desirable traits such as pest resistance, higher nutritional value, or enhanced growth. Because these traits are introduced into a plant's or an animal's genetic makeup, they are transferable to the next generation. Although both plant- and animal-based food sources have been genetically engineered, the influx of GMOs into the food system has resulted mostly from plants, primarily maize, soybean, and rapeseed.

GMOs have been deemed the "fastest adopted crop technology in the history of modern agriculture" (James, 2011). The first GM crops (corn and soybean) were introduced into the US market in the mid-1990s and between 1996 and 2011, there was a 94-fold increase in hectares planted with GM crops worldwide (1.7 and 160 million ha, respectively) (James, 2011). According to Holst-Jensen et al. (2012), there are dozens of GM species in the market or in the pipeline, and there has been a large increase in the number of countries growing GM crops, the diversity of traits being introduced and global trading of GM products.

There has been intense debate, especially in the decade and a half since 2000, between those advocating the advancement of GMOs and those opposed to either the production of GMOs or their marketing (or both). Those advocating for widespread use of GMOs argue that GM foods pack both environmental and health benefits. In theory, yields from GM crops are better and farmers could use fewer chemicals if plants were pest resistant. If GM fish or livestock are treated to mature faster or produce larger edible parts, the environmental destruction caused by overfishing or factory farming may be reduced. In terms of health benefits, GM foods can be engineered to be more nutritious and plentiful, thereby helping to alleviate world hunger and malnourishment.

Those opposed to GMOs argue that such outcomes have not been realized. Rather than requiring fewer chemicals, insects, viruses, and bacteria become resistant, resulting in the need for new chemicals to fight new diseases and continuous genetic reengineering, often involving multiple ('stacked') transgenetic traits (Buiatti et al., 2013). Of major concern is gene flow between GM crops and non-GM crops, and the resulting reduction of biodiversity. Inevitable gene flow also has threatened conventional and organic farmers (the biotech corporation Monsanto sued over 100 farmers in North America for patent infringement because Monsanto-patented seeds drifted into these farmers' fields); this is especially problematic for organic farmers because a US ruling determined that certified organic products cannot contain GMOs. From a health perspective, there has been increasing concern about the possibility of gene transfers into humans such as allergens, unhealthy or even fatal bacteria in the gastrointestinal tract, or into human cells (Buiatti et al., 2013). The introduction of GM foods into the world market has also not made a serious dent in world hunger or malnutrition. While crop productivity has increased, the USDA acknowledges that this was the result of shifts in industrialized farming practices, not GMOs (Buiatti et al., 2013: p. 265). Further, GMO crops tend to be produced and consumed in the richest, not poorest, countries.

Worldwide, there are widely different approaches to the introduction of GMOs in the market. At one end, there are countries such as the United States where GM crops have been widely adopted and introduced into a wide variety of food products with no labeling and no reliable method available to consumers for tracking GMOs in their foods. At the other end are countries such as France that have approached GMOs with considerable skepticism, banning certain GM crops from production and all GM animals from market (EFSA, 2013). Although few countries ban imports or cultivation of GM foods, as of 2013, 64 countries including China, Japan, Brazil and all of the EU members required labeling of GM foods (Center for Food Safety, 2013).

Permaculture

A growing movement surrounding food production is *permaculture*. The concept behind permaculture – permanent agriculture or permanent culture – is developing self-sustaining systems that operate according to natural laws. Despite its roots in natural systems that existed for millions of years, the practice of permaculture marks a radical shift from other AFMs and certainly conventional farming practices. For example, just as one is unlikely to observe monocrops in nature, in a permacultural landscape, animals, plants, and humans exist cooperatively. Rather than operating from the view that nature is an enemy, a view common in modern agriculture (e.g., 'weeds' and 'pests'), permaculturalists work with nature rather than against it to build a sustainable

ecosystem that "uses and melds the best features of whatever is available to it," even waste (Hemenway, 2009: p. 5). In permaculture, waste products become resources, as in collecting water runoff from an air-conditioning system to water plants or using garbage to create fences.

Although the concept originated in the early twentieth century, its recent emergence can be traced to the work of Bill Mollison and David Holmgren in Tasmania. Their observations of the rainforest, one of the richest ecosystems on earth, led to the proposition that human communities can be developed to be as sustainable, productive, and rich as those found in the natural world. Permaculture is about design rather than any particular method or system. Hemenway (2009: p. 5) suggests that "If we think of practices like organic gardening, recycling, natural building, renewable energy, and even consensus decision-making and social-justice efforts as tools for sustainability, then permaculture is the toolbox that helps us organize and decide when and how to use those tools."

Permaculture has been adopted on small scales such as backyard landscapes, as well as regions or countries. Cuba, for example, turned to permaculture after the collapse of the Union of Soviet Socialist Republics (USSR) (its main trading partner) and the United States tightened embargos on food imports to Cuba. According to Roberto Perez (The Permaculture Research Institute, 2013), faced with a hunger crisis, Cuba turned to sustainable farming and now leads the world in permaculture. In other cases, deserts in the Middle East have been greened through basic permaculture techniques. The success of such programs and their focus on sustainability are likely to make permaculture one of the most important global food movements of the future, spurred on by grassroots activists working to help communities ravaged by war, poverty, and environmental degradation, or cut off from the land by urban development and industrial agriculture.

Food Justice

Many AFMs have been criticized for ignoring racial and class inequalities, and failing to recognize that disadvantaged groups and communities are most likely to be harmed by current practices (Alkon and Agyeman, 2011). For instance, CAFOs are disproportionately located in areas populated by low-income and non-White residents, and these facilities further depress local economies by concentrating profits into the hands of a few rather than spreading them throughout the community (Kelley et al., 2007). Poorer communities have limited geographical access to healthy foods and are less able to afford them. Farm workers are disproportionately people of color while those who benefit from the system (owners and managers) are predominantly White (Carrasquillo, 2011; USDA, 2013d). The 'food justice movement' attempts to bring these inequalities to light, and places emphasis on fair trade, localism, affordability, equity, and justice (Alkon and Agyeman, 2011).

According to Wekerle (2004), there are three strategies used by the food justice movement to address these injustices. First, it emphasizes the local- and community-based initiatives, drawing on local food movement practices (community gardens/kitchens, youth education, etc.), in order to promote food security from the ground up. Second, it seeks to engage in local, regional, and national policy making and planning to promote access to healthier foods for all. Third, it seeks to create a 'networked food justice movement' that is fluid yet able to exist with limited funding and structure (Wekerle, 2004: p. 381).

There are many such groups, each with its own agenda, messages, and goals. For example, the *Growing Food and Justice Initiative* is a multiracial coalition that works to create sustainable food systems by and for people of color, such as a group of Latino/Latina gardeners in South Central Los Angeles who grow foods indigenous to their native cultures, such as corn, beans, and squash, and participate in transnational seed exchanges (Alkon and Agyeman, 2011). Other food justice groups may target different problems or populations. For instance, *Fair Trade USA* works to ensure that workers earn decent wages and that farmers receive a fair price for their goods (Fair Trade USA, 2013). *Food Not Bombs* cooperate with local groceries and bakeries to collect unsold vegan foods and prepare and serve these to individuals in need. Despite its range of focus, what identifies the food justice movement is empowerment of and coalition building among those groups most negatively affected by contemporary practices.

Challenges and Considerations

Because food is so central to identity, culture, history, and health, and conventional agricultural practices are widely understood as unsustainable, AFMs will continue to grow in numbers and influence. There are clear challenges, however, most notably the AFMs' ability to address "issues of equity, food security, class, gender, and race" (Goodman, 2000: p. 217). Many of the people who are able to participate in alternative food practices (obtaining local, organic, and/or non-GMO food at FMs, CSAs, or from their own lawn and community gardens) are not those most affected by the industrialized food system. Many involved in food movements emphasize educating people which can result in 'telling others what to eat,' rather than focusing on access, affordability, and structural inequality that make AFMs unsustainable and difficult to develop (Allen et al., 2003; Guthman, 2008: p. 436). Furthermore, while participation in alternative food has grown rapidly and receives major support across the global North, alternative food is only beginning to be explored in the global South (Freidberg and Goldstein, 2010). Whether alternative movements will transform the way food is produced and consumed both locally and globally through sustainable, local, fair, and equitable practices is yet to be seen.

A central concern is whether the growing world's population can be fed through nonintensive farming methods and therefore whether methods promoted by AFMs are realistic alternatives to conventional 'factory farming.' Populations with resources and opportunities to participate in alternative food are more able to sustain themselves using nonintensive farming methods, while those less privileged must often rely on food that is produced from industrialized agriculture, such as GM foods. Thus, focusing on eliminating larger social disparities is key to feeding the world through sustainable, ethical farming methods, and

social movements, like AFMs, have been central to addressing these social problems. In this sense, what might make them successful – elimination of structural inequality rather than promotion of any specific farming method or consumption pattern – would also lead to their demise.

AFMs are not likely to replace or seriously challenge conventional, industrialized methods of food production (Lyson, 2004). However, industrialization and alternative food practices do not necessarily have to be mutually exclusive, on opposing sides of a political agricultural continuum. Jarosc (2008: p. 242) argued, "globalization of food is part of the development of local food systems." For example, urbanization is accompanied by more FMs and residents demanding access to local food (Jarosc, 2008). Also, AFMs have had enough impact on the economy that even conventional grocery stores carry organic, non-GMO, and local products. In the US alone, the USDA reported that annual local food sales were dollar;4.8 billion in 2008 (USDA ERS, 2012) and organic food sales were estimated at dollar;27 billion in 2012 (USDA ERS, 2013).

Despite the challenges AFMs face, they are likely to have an even stronger and visible presence in food production and distribution for years to come, particularly if they adequately address the biggest concerns and criticisms concerning their commitment to social justice and sustainability. As technological advancements in food production continue, the conventional food system will be faced with new challenges, prompting even more AFMs to emerge and confront changes brought on by these innovations.

AFMs will persist, as will questions about how these movements will operate and influence society in the coming decades. One area ripe for scholarship is the way technology will transform food systems and movements. One of the most interesting recent developments is laboratory-raised meat, meat that is grown by using stem cells. Since no animals are killed through this process, this development has implications for the environment, social movements, and identities. For instance, would introduction of lab meat substantially reduce global warming and devastation caused by CAFOs and fulfill the food revolutions' promise to reduce world hunger? How might this development affect the agendas and effectiveness of animal rights groups? Can one still be a 'vegetarian' if one eats meat raised in labs?

Other topics for research are the tensions between corporate and public interests surrounding health and food issues, and how these play out on national and global stages. For example, in 2014 General Mills announced that it would no longer use GM sugar and corn in Cheerios™, a decision most likely prompted by food advocates, and potentially forcing other corporations to follow suit, similar to that which occurred around the organic food movement. Further, if some countries adopt stricter laws concerning biotech foods, what impact will this have on corporations and markets in more lax countries such as the United States? It will also be interesting to analyze the shifting political economies surrounding food movements, including the roles governments play in supporting or opposing AFMs (and public health) and the power AFMs have (or do not have) to reshape the political economies at local, national, and global levels. Beyond the political and economic realms, AFMs may help transform social relations both globally and locally. As the risks associated with contemporary food systems intensify, we may see more cooperation and communication between the Global North and Global South around shared interests in safe foods. Thus, an area of concern is not only whether AFMs can address inequalities within wealthiest countries, but can and will they transform the relationships between wealthy and poorer countries?

Alternative Schools of Economic Thought

Peter J Boettke and Solomon M Stein, George Mason University, Fairfax, VA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Alternative schools of economic thought are defined relative to the current mainstream of economic theory. This article examines the path of mainstream economics during the twentieth century and the challenges presented to the mainstream by various alternative schools of economic thinking, such as the desire for relevance of American institutional economics, the emphasis on market process and calculation given by Austrian economics, the role of gendered theorizing examined by feminist economics, and the treatment of uncertainty offered by post-Keynesian Economics.

Introduction

Economic thought, contrary to the timeless picture presented in an introductory textbook, is a complex and heterogeneous set of ideas. At any given time, some of those ideas will be ascendant among economists, while other ideas and methods will be out of step with the economic profession at large. Alternative schools of economic thought arise from a desire to explore those out-of-favor ideas, either with a view to repair or replace the currently fashionable. What is considered alternative depends on what is considered to be in the current mainstream, which has varied in scope widely between the turn of the twentieth century and the present.

Mainstream Economics

Boettke et al. (2008) document the changes in the composition of the mainstream, arguing that economics entered the twentieth century with a relatively broad set of ideas and methods in the mainstream, drawing upon the origins of economics in the work of classical political economy. (This core of classical political economy, a focus on exchange and the institutions within which exchanges takes place within the subset of economics that Boettke, Leeson, and Smith call the 'mainline' and trace back to Adam Smith and continued through the classical political economists.) Beginning in the interwar years, the view of economics as an element of that broader political economy tradition that included other sorts of social science and philosophy fades in favor of an emphasis in pursuit of the logic and operation of formal equilibrium theory. The questions and approach to economics characterized in this work came to define the mainstream, with the synthesis of Keynesian macroeconomics and neoclassical, and general-equilibrium microeconomics. The dominance of this approach in mid-century academic economics necessitated in turn the rediscovery of the broader set of questions of political economy, often in the context of particular fields or approaches, such as transaction cost economics, New Institutional Economics, or game theory. These approaches, along with other challenges both to the Keynesian macroeconomic paradigm and to the exclusive focus on general equilibrium in microeconomics, led over time (Perhaps, 'funeral by funeral.') to a mainstream inclusive again of broader approaches and to a lesser extent, a broader set of acceptable methods. As Boettke and Prychitko (2011) recount, the culture of economics in the 1980s was one that reflected this re-expansion of the scope of mainstream economic scholarship.

With this pattern of a broader set of questions and methods condensing into the neoclassical-Keynesian synthesis and then gradually broadening back out to find room for emerging (or perhaps, returning) fields in the later part of the twentieth century, it may be unsurprising that many of the well-developed 'schools' of alternative approaches to economics arise during the period when there was comparative openness to acceptance of new ideas in general; both those approaches that existed alongside what became the mid-century mainstream and found themselves suddenly on the outside looking in, such as the Austrians and American Institutionalism, or those approaches which represent views that, rather than being absorbed into the broader mainstream of the 1980s onward, remain self-consciously opposed to elements of current mainstream practice. The rest of this article focuses upon these groups individually, identifying their origins and how they see themselves as distinct from the current mainstream. While this is by no means an exhaustive list of heterodox thinkers or their ideas, it should give a good indication about the puzzles alternative approaches offer to the mainstream regarding theory and method.

American Institutionalism

Institutional economics refers to a group of American economists in the early twentieth century who to greater or lesser extent dissented from the state of neoclassical economic theory. The most prominent thinker now associated with this tradition is Thorsten Veblen, best known for *The Theory of the Leisure Class* (Veblen, 1899). While Veblen is the most prominent thinker associated with Institutionalism, as Rutherford (2011) recounts, his work was eccentric and considered inspirational, rather than central, to the larger community of economists interested in the institutional program. This community was critical of the neoclassical theory for being primarily focused upon equilibrium statics and resting upon unrealistic (that is, primarily hedonic) psychological assumptions. Instead of this 'value theory,' institutional economists saw themselves as concerned with the role of real-world institutions in shaping

economic reality, understanding institutional (particularly legal) evolution, and operating using more solid 'scientific' foundations both in terms of psychology and methodology.

In the paper that definitively established 'institutional' economics as the label attached to this school, Hamilton (1919) outlines five criteria on which he thought any set of ideas that could be called 'economic theory' ought to be judged. His criteria and why he saw value theory as falling short of their accomplishments present a succinct statement of the critical view of neoclassical theory held by institutional economists. Firstly, Hamilton (1919: p. 312) argued that "economic theory should unify economic science," by which he seems to mean theory should be able to include each field in which economists do research, arguing that 'value theory' does not reach into the majority of applied fields. Secondly, Hamilton (1919: p. 312) argues for relevance in economic theory, particularly to what he calls "the modern problem of control" in comparison to "a mere search for hypothetical truth" which he sees as being central to the abstract theoretical concerns of neoclassical economics. In his interpretation, theoretical development both in the classical economists' time and in his own was driven by the desire to answer questions of policy relevance, such as Ricardo's interest in monetary theory or (as we will see later in this article) the concern of the Austrian economists with the socialist calculation debate. Similar to those concerns, he argues that the relevant world-state which economic theory ought to be developed to answer is the "general demand for control" (Hamilton, 1919: p. 313). His third argument is that, given the two above claims, institutions are the appropriate level of analysis for economic theory. For Hamilton, this means an understanding of the particular forms of industrial society such as the particulars of corporate organization to understand the theory of the firm (in contrast to the more abstract view of neoclassical price theory) and places a strongly constructive emphasis: these particulars "must be recognized by one who would direct, or, if he be an economic theorist, watch, industrial development" (Hamilton, 1919: p. 314). Fourth, economics ought to see these institutions as a process, capable of conscious direction. (As we will see later, this view of process as meaning that it is amenable to rational construction provides an interesting contrast with the implications of the market as a process for Austrian economics.) Finally, Hamilton (1919: p. 316) calls for a grounding of economic theory in "an acceptable theory of human behavior," that is one built on what was considered to be the state of the art in psychological theory at the time. (This call for psychological realism closely resembles those made for the modern development of behavioral economics. Interestingly, the decline of institutional economics was based at least in part on a conception of them as being devoid of a systematic alternative theory to neoclassical economics, and excessively ad hoc in their introduction of psychological or institutional factors, a critique similar to that raised at behavioral economics by critics such as Posner (1998).)

In developing their alternatives, these considerations led many institutional economists to emphasize psychological theories such as instinct and habit psychology or Skinnerian behaviorism, often to critique marginal utility theories of consumption and to favor instead psychological theories of consumption formation. Institutional economists were also concerned with what Rutherford (2011: p. 47) describes as "a conception of the industrial economy as dominated by pecuniary or business interests" in a way that definitively shaped economic activity and thus provided a superior frame of reference than neoclassical price theory. Particular focus was given by economists working in the institutional tradition to the impact of ongoing technological change during the interwar period, such as J.M. Clark's work on the impact of overhead costs (Clark, 1923) and extensive work on labor unions (Commons, 1913, 1919).

One other significant commonality within the institutional movement was a focus on the role of economics as a *tool* of social control, (Over and above the idea that the questions of economics ought to deal with questions of control as suggested by Hamilton, this meant that the purpose of examining these problems was to actively apply the results to policy.) particularly within a turn-of-the-century progressive framework. Institutional economists saw social control as central to the project of economics in their day, and their ideas of what constituted a scientific approach to solving such problems was primarily empirical and quantitative and were central in the founding of institutions devoted to collecting the data needed to pursue this project, most notably the National Bureau of Economic Research (NBER), where Wesley Mitchell, a prominent institutionalist, was appointed Director of Research upon its founding in 1920. However, by the middle of the 1930s, the appeal of the institutional program had faded, and it was increasingly criticized as being unable to offer a systematic alternative paradigm to replace the neoclassical value theory they saw as unsatisfactory. The dominant view of the institutional program in retrospect, advanced by historians of thought such as Blaug and Stigler, reflected this view of a group unified only by dissent, but that view has been challenged recently by Hodgson (2004) and Rutherford (2011).

The Austrian School

The Austrian school of economics was founded in 1871 with the publication by Carl Menger of his *Principles of Economics*. Menger's goal in the publication of his *Principles* was twofold: it contained both an exposition of economics based upon marginal utility theory, which along with the work of Jevons and Walras would lead to the marginal revolution in economic theory, along with defending the idea that economic theory was a universally applicable approach to understanding human behavior. While the scope of economic investigation has been a subject of debate both within economics (For a summary of the ideas of economists on this point over time, see Kirzner (1960).) and between economists and other social scientists, there has seldom been an environment where Menger's statement could have been more controversial than the German academy of his day, where the dominant view was that of the German Historical School, which thought that economic behavior was historically contingent, and that particular epochs of historical development contained their own internal economic logic.

Menger and his Historical School colleagues became embroiled in a debate known as the *Methodenstreit*, or dispute

over method, during which Gustav Schmoller gave Menger and his followers the label 'Austrian School' as a means of belittling them relative to the 'German' historical school, which has stuck since. With respect to other marginalist economists, however, Austrians during those early years saw themselves as part of the broader economic tradition. During the interwar years, key debates within economics saw the Austrians, led by Ludwig von Mises and F.A. Hayek, develop as an increasingly distinct school of thought. The two most prominent of these debates were the debate over Socialist economic calculation and the debate between Hayek and Keynes over monetary policy. In both cases, in the eyes of the economics profession, the Austrian position was seen to be the losing one. Austrian economists in the wake of these debates (and, as a consequence of the Second World War, no longer in Austria) had to reconsider their relationship to the broader economics profession and found themselves increasingly out of step with the mathematically formalist and Keynesian mainstream of the 1940s and 1950s.

Interest in Austrian economics surged in the early 1970s, spurred by the publication of Israel Kirzner's *Competition and Enterpreneurship* in 1973, followed by Hayek's receipt of the Nobel Prize in Economics in the subsequent year. This Austrian revival began as centered on those scholars, as well as the work of Murray Rothbard, Ludwig Lachmann, and others. Along with those scholars, modern Austrian economists draw inspiration from many modern figures in economics who they see as working to return the mainstream of economics toward the mainline, such as Armen Alchian, James Buchanan, Ronald Coase, Harold Demsetz, Elinor Ostrom, Axel Leijonhufvud, Douglass North, Mancur Olson, Vernon Smith, Gordon Tullock, Leland Yeager, and Oliver Williamson.

Boettke (2008) presents ten propositions that broadly capture the substantive beliefs of Austrian economists about economic method and theory. They are as follows:

1. Only individuals choose:

This captures the idea that economics is what Mises (1948) called a *Praxeological* science, that is, it studies the behavior of acting persons, as only individuals make choices. Economics renders these choices intelligible and seeks to understand the unintended consequences of choice.

2. The study of the market order is fundamentally about exchange behavior and the institutions within which exchanges take place:

Within Praxeology, the science of human action, is the study of exchange, *cattalactics*, which places a focus away from what Buchanan (1964) called the allocative paradigm which sees the maximization problems of scarce means and competing ends as the primary focus of economic investigation, and toward the exchange paradigm which focuses more on the process of market behavior and the institutions within which exchange takes place.

3. The 'facts' of the social sciences are what people believe and think:

Since the subject matter of economics is human action, attempts to eliminate the subjectively understood meaning that actors place on their activities seems to the Austrian approach to remove the important content from activities. Austrian economists see the measuring stick for progress in economic science as rendering behavior intelligible, rather than purely by predictive power, rejecting the argument of Friedman (1953).

4. Utility and costs are subjective:

While the proposition that utility is subjective is one of the core elements of the neoclassical theory of value, Austrians reject the Marshallian position that costs are in some way objective. Since supplies of goods are based upon the alternative uses of scarce resources, and those alternative uses are subjectively determined at the moment that those resources are allocated to one use over an alternative, cost is just as subjective as value.

5. The price system economizes on the information that people need to process in making their decisions:

As most clearly stated by Hayek's 1945 article 'The Use of Knowledge in Society,' the price system functions as a method of information transmission, in which the price of any given item communicates knowledge regarding the conditions of the market in that item without any given actor needing to acquire any knowledge besides the price. This includes even items of local or tacit knowledge that could not be acquired by other means.

6. Private property in the means of production is a necessary condition for rational economic calculation:

Stemming from the socialist calculation debate of the 1920s, Austrian economists see private property and profit and loss as necessary conditions for economic resources to be rationally allocated. Mises's argument was that, absent this private ownership of capital goods, there would be no market in those goods, resulting in no money prices, without which there could be no way to determine the exchange ratios between capital goods required for rational calculation.

7. The competitive market is a process of entrepreneurial discovery:

Rather than the notion of competition as a static condition of a state of affairs, Austrian economics focuses upon the process of competition. The competitive market is characterized by constantly changing plans, as entrepreneurs search for new combinations of resources that will yield them additional profit. The feedback of actually realized gains and losses from these speculative activities brings the market closer to a situation of full coordination, while errors by those entrepreneurs create the opportunity for future correction.

8. Money is non-neutral:

Money, the commonly accepted medium of exchange, is a central component of the market process, since it functions as the unit by which prices and profit and loss are calculated. When government policy distorts the monetary unit, the whole system of prices, and thus the communication of information across the economy, is distorted along with it. Although changes in the monetary unit eventually lead to adjustments in prices to account for the change in monetary policy, these changes do not occur instantly or evenly throughout the economy, so money cannot be neutral.

9. The capital structure consists of heterogeneous goods that have multispecific uses that must be aligned:

Austrian economists stress the importance of dealing with capital as heterogenous and with multiple uses, which must be aligned into a structure of production. Production requires investment now for an uncertain future, and the value of those capital goods is determined by their ability to satisfy the final goods they will eventually be used to produce. The heterogenous nature of capital goods and their imperfect substitutability means that any given system of prices renders some alignments of capital profitable, and if revealed to be in error, cannot be costlessly reversed. Instead, resources will be lost in the meantime as costly realignments of capital take place.

10. Social institutions often are the result of human action, but not of human design:

Austrian economists view institutions as a central element of human activity, and emphasize the role of processes in economics, but in contrast to the emphasis on those ideas in American institutional economics that saw those facts as making economic activity amenable to social control, Austrian economists stress that many of these institutions are not the products of conscious direction, but rather emerge out of the unintended interaction of all the various human actions undertaken. The market is the paradigmatic case of such an unintended emergent result of individual action: no actor sets out to create the price system or to coordinate all economic activity, but rather to remove their felt uneasiness or improve their own position via exchange behavior. These 'invisible hand' phenomena are not restricted to the market, but have been fruitfully used as a way to understand law, language, scientific progress, and numerous other social phenomena.

These ten propositions provide a useful view into the propositions regarding the nature of economic theory and how to understand examination of human behavior that Austrian economists tend to emphasize. The degree to which this emphasis is seen as compatible with existing mainstream approaches varies significantly, leading to a lively internal debate on the role of even fundamental concepts, such as equilibrium, in praxeological approaches to economics. (For a defense of the usefulness of equilibrium, see Kirzner (1992), while for a defense of a non-equilibrium (in contrast to disequilibrium) economic approach see Buchanan and Vanberg (1991).)

Feminist Economics

The most recent of the alternative schools considered here, feminist economics only developed into a school of thought within economics during the early 1990s, after having been an approach in other social sciences for several decades. As feminism became a distinct movement and approach in the academy, scattered efforts were made to present a feminist critique of neoclassical theory. However, feminist economics as an organized alternative school emerged out of a conference at the American Economic Association in 1990, resulting in the formation of the International Association for Feminist Economics and the founding of the journal *Feminist Economics*.

Julie Nelson's 1995 article titled 'Feminism and Economics' in the *Journal of Economic Perspectives* presents an overview of the emerging field, outlining the challenges that a feminist approach to economics (as opposed to the perhaps more common feminist critiques of economics from outside the discipline) presents to economic theory. Drawing upon feminist arguments that the history of philosophy of science is dominated by a gendered perspective whereby the values of science have been associated with masculinity, feminist economics as presented by Nelson would try to move beyond this gendered set of judgments that associate 'masculine' economics with the preferable state of economic investigation. She outlines four areas where a more balanced, feminist view of economics would improve economic investigation: modeling, method, topic selection, and teaching.

In model development, Nelson argues that, at least for the most part, economic models reflect a particular conception of autonomous individuals who are always rational choosers, and never undergo periods where they require care for others, such as infancy or old age, and incorporates motivations such as fairness and dependence. She is critical of the defenses of traditional economic theory against these additional behavioral assumptions by economists such as Gary Becker or Bob Lucas on the grounds that their restriction of economic theory to models of *homo economicus* "are not, as they are often taken, statements of demand for high rigor, but rather are demands that androcentric biases be indulged" (Nelson, 1995: p. 137).

Nelson is similarly critical of the importance placed on mathematical formalism (a recurring theme in most alternative approaches to economic theory) and the logical purity of mathematics instead of the 'messy' empirics of less sophisticated statistical techniques or survey data, seeing the discomfort with these supposed losses of objectivity in data as stemming from a flawed, Cartesian notion of what constitutes objectivity and truth in science. Instead, to the feminist perspective being able to outline one's own framework at the outset and then proceed with the analysis is preferable to purporting to a false standard of detachment and objectivity.

With regard to topic selection, Nelson laments the general absence of families and activities generally undertaken outside of the market from the consideration of economic analysis, and notes that many feminists are skeptical of the value of the notable analysis of the family undertaken by Gary Becker. This neglect of the family is also evident in the composition of GDP, where predominantly female-undertaken domestic production is omitted, or in the treatment of human capital as predominately regarding the decisions of young adults considering the marginal personal investment in education, omitting previous decisions that shape human capital. Finally, a feminist approach to economics suggests an alternative pedagogical style with more of an emphasis on participatory, applied teaching which could contribute to a climate which induces more women to enter economics as a discipline, as opposed to being 'selected out' by androcentric theories that suggest that "economics is not for (or about) me" (Nelson, 1995: p. 146).

Along with presenting a feminist perspective on the state of mainstream economic approaches, feminist economists tend to be concerned with topics where they perceive the mainstream as neglecting such as the aforementioned domestic or

care work, or of general importance to feminists such as the impact of economic development and labor market inequalities, as well as examination of the gender distribution of economics itself.

Post-Keynesian Economics

The beginnings of post-Keynesian economics rest in the dissatisfaction with some economists who considered themselves followers of Keynes' theories from *The General Theory* with the neoclassical Keynesian synthesis that had become (as discussed earlier) the mainstream approach to understanding and applying Keynes' ideas. Building upon the work of Joan Robinson, Roy Harrod, Nicholas Kaldor, Michal Kalecki, and others, Eichner and Kregel (1975) presented post-Keynesianism as an alternative economic paradigm, citing as its unique features the role of history and time, placing theoretical importance on the distribution of income as contributing to economic outcomes, and more faithfully retained the approach to understanding a money economy contained in Keynes and in its acceptance of alternate (generally less restrictive) microeconomic foundations relative to neoclassical price theory. *The Journal of Post-Keynesian Economics* followed soon after in 1978.

Accompanying the substantive positions outlined by Eichner and Kregel and the extension of their project to present a more authentic Keynesian system, (For a survey of the state of the art in post-Keynesian modeling, see Asensio et al. (2012).) post-Keynesians have been vocal critics of neoclassical theories of macroeconomics, especially endogenous growth models and New Keynesian macroeconomics, as well as other elements of neoclassical theory based on their omission of the role of fundamental uncertainty on the real world.

Paul Davidson's *Reality and Economic Theory* (Davidson, 1996) presents a good summary of the post-Keynesian approach to uncertainty, as well as the view of reality post-Keynesian economists believe to be held by alternate approaches. "Most mainstream economists today," Davidson argues, "accept as a universal truth the existence of a predetermined reality that can be fully described by unchanging objective conditional probability functions" (Davidson, 1996: p. 479). This renders future outcomes (stochastically) predetermined and enables rational decisions by assuming (correctly) that a sample of the past and present represents also a sample of the future. In contrast to that model, Davidson presents Keynes as developing a model wherein individuals recognize some creative element to the future. For Davidson, almost all theories outside of the work of Keynes, American institutional economics, and post-Keynesianism rely upon an immutable reality at some point, if only in the long run. Acceptance of the (post-)Keynesian conception of a transmutable reality renders intelligible for Davidson the purpose of accumulating liquidity one does not intend to expend as a hedge against the permanently uncertain future. Uncertainty of this type also leads to the presence of what G.L.S. Shackle termed "crucial decisions," which create effects that render the original decision non-repeatable, the making of which is to Davidson the key entrepreneurial function. Far from being purely methodological concerns, for Davidson these distinctions have important relevance for economic policy, with the transmutability of the world implying an absence of a tendency to return to full employment, requiring Keynesian demand policies, which in turn would require some form of anti-inflation policies to stabilize the system.

Of the alternate schools considered here, Post Keynesians are perhaps the most self-consciously heterodox (although elements of the Austrian school also embrace heterodoxy) although recent work on the relationship of heterodoxy published in post-Keynesian journals (notably Colander et al., 2007, responding to Dequech, 2007) has urged self-consciously heterodox economics to focus less upon defining themselves with respect to 'neoclassical economics' and focus on commonalities with economics in general.

Conclusion

All the schools considered here share two defining features that, to a greater or lesser extent both by individual author within the school and over time, keep them from becoming part of the mainstream of economic thought. The first is that they are in general critical of at least some aspects of the language of mainstream economics itself, making adaptation of their arguments into the conventional style of the mainstream more difficult than for other approaches which, despite differences of method or topic nevertheless have become part of the mainstream. Secondly, at least at the level of the ideal-type of a school, each of these alternative approaches are (or were) seen as advocates for some particular set of policy prescriptions. While policy relevance is not itself a disqualification from the mainstream, the combination of a distinctive policy association and criticism of the mainstream approach can lead to a perception of these schools as advocacy as against a (perhaps illusory) objective approach to scientific investigation.

Alternate schools of economic thought such as those discussed earlier are distinct not only from the mainstream but also from alternative theories about economic topics, in that even in their criticism of various aspects of mainstream economic theory, even on fundamental issues these schools are still attempting an 'economic' approach to understanding a particular issue, in contrast to a non-economic approach to an issue within the economy. (While Austrians, post-Keynesians, Institutional Economics, Feminist Economics, and other alternative schools might disagree with the mainstream and with each other over the relevance of power relationships to labor demand, for example, none are attempting to see labor through some other category, as one might do viewing it as a Hegelian dialectic or considering labor markets from a religious or ethical perspective.) Finally, despite an attempt to present each school's subjectively perceived element of distinctiveness with respect to the mainstream, each of these groups of scholars is a highly non-homogenous and non-static classification, just as the 'mainstream' of economics represents a complex and dynamic body of methods, topics, and theories. Within each of these schools exists a lively debate on where exactly the fundamental aspects of their critique of the current

mainstream lie within their body of theory, the appropriate margins to repair or reject mainstream approaches, and the strategy by which to accomplish their goals, both academically and socially oriented.

Abstract

Prosocial behavior involves costs for the self and results in benefits for others. Altruistic acts confer benefits to others, but net costs to the self. Different types of prosocial behavior are distinguished, depending on whether it is enacted by an individual or as part of a group effort, and whether it is first order (direct contributions) or second order (sanctioning) behavior. Six theoretical approaches are outlined (evolutionary, rationalist, structural, institutional, situational, and individual differences). They explain the evolution of prosocial behavior and its variation across groups, contexts, and situations. Avenues for future research are discussed.

Introduction

Prosocial behavior has intrigued scholars for centuries, including prominent academics in the early days of economics, political science, anthropology, and sociology. In the *Theory of Moral Sentiments*, Adam Smith (1759) asked "which principles in his nature interest him in the fortune of others?," answering that sympathy for the misery of others was the answer. Alexis de Tocqueville (1835) suggested the hypothesis that the possibility to have influence through local democracy motivated the community spirit of Americans. More generally, research on prosocial behavior attempts to explain (1) why and how prosocial behavior evolved in humans and (2) why and how the incidence and forms of prosocial behavior vary across individuals, groups, and situations. The present article presents some of the more recent attempts to answer these questions. Since this article focuses on *sociological* explanations, particular attention is paid to the level of the group or larger collectives as potential antecedents, consequences, or contexts for prosocial behavior and altruism. We will first address some definitional issues and subsequently elaborate on the wide variety of different types of prosocial behavior. This is followed by an overview of different theoretical approaches to prosocial behavior. The article concludes with a digression on open research questions in the sociology of prosocial behavior.

Definitions

Prosocial behavior is a broad class of behavior defined as involving costs for the self and resulting in benefits for others. Where prosocial behavior results in *net* benefits for both the beneficiary and the person committing the prosocial act, it is referred to as *mutualism*. Where prosocial behavior benefits others but confers *net* costs to the person committing it, prosocial behavior becomes *altruism* (Bowles and Gintis, 2011). A common distinction is made between pure altruism and impure altruism. Pure altruism is "acting with the goal of benefitting another" (Piliavin and Charng, 1990); prosocial behavior solely motivated by concern for others, also denoted as 'altruistic motivation.' Impure altruism is prosocial behavior motivated by more self-centered motives or even by narrow self-interest, potentially in addition to concern for others. Note that the definition of prosocial behavior is purely behavioral, while altruism combines behavioral and motivational elements.

Types of Prosocial Behavior

Prosocial behavior can take many different forms, depending on the context in which it takes place; it may benefit specific others, known or unknown and at varying degrees of social distance, ranging from close kin to total strangers; it may benefit social groups of which the actor is a member or not, as well as society as a whole or abstract ideals.

Much specialized research on prosocial behavior can be found, focusing on prosocial behavior in specific societal and institutional contexts. Since this research often uses different labels to denote the phenomenon, reviews of research findings face serious challenges, even within a single discipline. For example, within the field of the sociology of organizations, one specific form of formal prosocial behavior is organizational citizenship behavior, defined as prosocial extra-role behavior by employees of an organization benefiting colleagues or the employer (Podsakoff et al., 1997). Another aspect of prosociality recently studied in a specific organizational setting – public administration – is public service motivation, defined as "an individual's orientation to delivering services to people with the purpose of doing good for others and society" (Perry et al., 2010). Another challenge results from the fact that the analytical distinctions between the general theoretical constructs used to describe prosocial behavior are not always clear-cut, and seem to vary between disciplines; concepts like cooperation, solidarity, cohesion, collaboration, support, or help are often used as synonyms.

The following more general distinctions are particularly relevant for theory and empirical research. First, prosocial behavior can differ depending on whether it is enacted by an individual or as part of a group effort, and the effects it has on the beneficiary as well as on third parties. Four types of prosocial behavior can be distinguished based on these two dimensions. First, there are prosocial acts carried out by a single individual, benefitting a specific other individual. This ideal typical form is the implicit assumption of most analyses of prosocial behavior. Examples are passers by donating money to a beggar or doing the grocery shopping for your sick neighbor.

Second, there are prosocial acts carried out by a single individual, benefitting a collective or 'generalized other.' Examples are donations by an individual to a charitable organization, or a soldier holding a lost position to enable his squad to retract, but also less dramatic acts like paying one's taxes. Third, there are prosocial acts carried out by a collective in order to benefit a single individual. Examples are actions targeted to liberate political prisoners by organizations like Amnesty International. Finally, there are prosocial acts carried out by a collective or group, with the intention to help another collective. This kind of prosocial behavior can also be directed to benefit the collective itself. An example would be workers joining a wildcat strike at the risk of being fired (Zetka, 1992).

While benefitting a specific individual or group, prosocial behavior can also have positive or negative consequences for third parties. For example, forms of oppositional solidarity like strikes may benefit the participants, but harm the organization. Conversely, prosocial behavior favoring a specific individual or group may also benefit other groups, as in the case of strikes by a small group leading to pay raises for all employees.

A second important distinction differentiates between formal and informal prosocial behavior. Actions that involve an intermediary organization, like charitable giving, volunteer work for nonprofit organizations, or blood and organ donation are examples of formal prosocial behavior. Social and emotional support to friends and family members, caring for parents and children, or helping strangers are examples of informal prosocial behavior.

Finally, in settings of collective good production, first and second order prosocial behavior needs to be distinguished (Heckathorn, 1996). First order prosocial behavior consists of acts that directly benefit another individual or group. Second order prosocial behavior consists of acts sanctioning behavior that violates rules about prosocial behavior (Fehr and Gächter, 2002). In both cases, an individual can decide to cooperate or defect, but in the second order case, a third option is to oppose sanctioning of others. In situations of collective good production, the combination of first and second order decisions results in different types of prosocial behavior. Individuals who act prosocially by contributing to first-level collective good production can either be *full cooperators* (if they also sanction free riders who do not contribute to the collective good), *private cooperators* (if they refrain from sanctioning free riders), or become part of the *compliant opposition* by defending "the rights of others to refuse to contribute" (Heckathorn, 1996: 254). Individuals who do not contribute to the collective good at the first level can nevertheless decide to behave prosocially at the second level by sanctioning those who also did not contribute, thereby becoming *hypocritical cooperators*. They can also decide to actively oppose attempts of control by others (*full opposition*), or simply also not sanction free riders (*full defection*).

Theories of Prosocial Behavior

Several broad classes of theories explaining prosocial behavior can be distinguished. They advance different mechanisms to explain why prosocial behavior emerged in humans, and why it varies between individuals, groups, contexts, and situations.

Evolutionary approaches have demonstrated that prosocial behavior toward close genetically related family members could be the result of natural selection, because it may ultimately help to spread the benefactor's genes. Some scholars, therefore, suggest referring to prosocial behavior toward close relatives not as altruism, but as mutualism (Bowles and Gintis, 2011). A challenge for evolutionary approaches consists in the fact that prosocial behavior often extends far beyond the circle of close relatives. This observation is at the basis of an ongoing debate about human nature, i.e., the degree to and conditions under which human behavior is motivated by selfishness. Five evolutionary mechanisms are assumed to have made humans a cooperative species (Nowak, 2006): kin selection, direct reciprocity, indirect reciprocity, network reciprocity, and group selection. These mechanisms would also explain why we so frequently observe altruistic punishment; since it is an effective instrument safeguarding altruists from being abused, punishment of free riders became an objective in its own right. Along these lines, recent scholarship points to the hard wired character of *social preferences*, i.e., the fact that humans care for the well-being of others. Humans feel guilt and shame if they defect, feel obliged to help, and derive psychological benefits like pleasure and satisfaction from committing prosocial acts (Aknin et al., 2013; Konow and Earley, 2008), even if – or because – this comes at considerable costs. This holds not only for first order prosocial behavior (Jacquet et al., 2011), but also for its second order version; a series of influential experiments has shown that humans not only tend to develop negative emotions against free riders, but are actually willing to incur considerable costs to sanction them (Fehr and Gächter, 2002). Given this cumulative evidence, evolutionary approaches increasingly turn their attention to the question why altruistic preferences became so widespread and 'outcompeted' unrestricted and selfish gain maximization as the major motive guiding human behavior.

Rationalist approaches focus on the puzzle why and under which conditions selfish individuals engage in prosocial behavior. Classical rational choice theories prefer explanations that do not need to assume social preferences, but that stick to the core assumption of gain maximizing individuals. In this perspective, most prosocial acts fall under the category of 'mutualism,' i.e., they benefit both the sender and the target. This is usually the case if the sender and the receiver of the prosocial act are in some form dependent on each other for the acquisition or joint production of valued goods or services. Since the realization of mutual gains often takes place in a sequence of exchanges, the first player acting prosocially usually faces a trust problem, since the benefactor may decide not to reciprocate. We discuss two important ways to solve such trust problems: selective incentives and signaling.

Selective incentives are rewards and punishments designed to induce prosocial behavior. They can have a formal and an informal basis. For example, firms try to elicit prosocial behavior (i.e., extra-role organizational citizenship behavior) through selective incentives in the form of performance-contingent reward schemes, which are assumed to align the interests of the organization with the interest of the employee. But also in primordial social groups, like families, friendship cliques, or other kinds of sharing groups interdependence creates the need for informal norms (Lindenberg, 1997), because individuals have an interest to make sure that the other party acts prosocially toward themselves. Here, selective

incentives may take the form of remedial norms and emerge in a bottom-up process (Ellickson, 1991). Hence, rather than referring to norms as an external cause of prosocial behavior, rational choice theories prefer to 'endogenize' norms by pointing toward structural interdependencies as an underlying root cause (see also the section structural explanations below).

Signals are traits and behaviors that reliably predict someone's trustworthiness (Gambetta, 2009). Signaling is a key mechanism in situations of information asymmetry between two or more parties. Such asymmetries arise where both parties have at least partially conflicting interests, and where reliable and valid information about the quality (e.g., skills, performance) and/or the intentions (e.g., motivation) of one actor is unavailable or difficult to observe for another actor. *Relational signals* are cues about the signaler's intention to initiate or maintain a mutually rewarding relationship with the receiver (Lindenberg, 2003; Wittek, 2003). Individuals who are effective in successfully producing such relational signals will be more likely to attract prosocial acts from other players. The efficacy of a signal depends on a variety of factors (Connelly et al., 2011), in particular their *observability* (intensity, strength, clarity, visibility) and cost. Whereas some signals are easy to observe (e.g., a philanthropist's donation to a humanitarian fund) others are more difficult to decipher (e.g., evolutionary accounts of depression have argued that signs of depression reduce aggressiveness of exchange partners). The *cost* of a signal (e.g., the size of a donation in relation to a philanthropist's capital) has long been considered as a major condition for its efficacy, but more recent accounts deemphasize the importance of costs and suggest that less-costly signals may also be relevant (e.g., a prime minister's apology for atrocities of previous governments). Other aspects of signals are (Connelly et al., 2011: 52) their *fit* ("the extent to which the signal is correlated with the unobservable quality"), their *frequency* ("the number of times the same signal is transmitted"), and their *consistency* ("agreement between signals from one source").

Institutional approaches emphasize the importance of formal rules or informal norms and shared meaning as a root cause of prosocial behavior. In this framework, prosocial behavior does not require some ulterior payoff to the sender, but it can be the result of deeply ingrained cultural schemas, beliefs, values, or identities. Several mechanisms are often associated with institutional explanations of prosocial behavior. First, many scholars consider the *reciprocity* norm as a fundamental trait, which can be found in all human cultures (Mauss, 1954[1923]). The reciprocity norm requires that 'gifts'trigger the obligation to be repaid. This means that individuals receiving a gift from someone will be inclined to behave prosocially toward this person at a later stage (Gouldner, 1960). Reciprocity can take several forms, ranging from direct reciprocity (in which the beneficiary is the individual who provided the gift), to indirect or generalized reciprocity (where the beneficiary may be a third party). Second, institutional approaches consider *learning and socialization* as powerful triggers of prosocial behavior. Third, shared social identities may trigger feelings of in-group obligation and loyalty, which reduce the incentive to free ride (Ellemers et al., 2002).

Structural approaches: Two interrelated strands of research can illustrate this type of explanation. *Social dilemma* studies focus on the structure or 'anatomy' of the cooperation problem itself, pointing to *negative interdependence* and *scale* as two fundamental structural conditions that systematically affect the incidence of cooperation (Ostrom et al., 1999). The first condition of negative interdependence creates social dilemmas, such as, for instance, the prisoner's dilemma or the 'tragedy of the commons' (Hardin, 1968); everybody will be better off if everyone contributes, while it is individually rational to defect. Second, scale exacerbates free-rider problems, for the higher the *number of participants* (Olson, 1965), the smaller the impact of individual contributions will be on the collective good. Small-scale settings are often considered ideally suited to cooperation, because they guarantee frequent face-to-face contact and stimulate adherence to the social norm (Ellickson, 1991).

Social network researchers have studied how repeated interaction can stimulate individuals to act prosocially toward others. This will be more likely if the parties concerned do have a history of previous exchanges and the prospect of future interactions (Buskens and Raub, 2013). Repeated interaction allows for conditional cooperation and helps to build reputations. Conditional cooperation is considered the simplest solution in a situation of repeated interaction. Reputations about trustworthiness can be built within a dyad, but can also be gathered from third parties through gossiping (Sommerfeld et al., 2007; Ellwardt et al., 2012). Though embeddedness in dense social networks can trigger prosocial behavior (e.g., Flache, 2002), this effect is highly context dependent. For example, self-managed work teams characterized by a high level of trust (i.e., first order prosocial behavior) may score low on second order prosocial behavior, i.e., exhibit a tendency to avoid monitoring and sanctioning noncompliance (Langfred, 2004).

Situational approaches emphasize the power of cues as a trigger for prosocial behavior. Such cues can have their roots in (changes in) the physical or environment an individual is exposed to at a given moment. According to *goal framing theory*, even subtle cues can have strong effects because they activate different types of goal frames, which push either gain, normative, or hedonic motivations into the foreground. For example, a series of field experiments testing the 'broken windows hypothesis' showed that prosocial behavior declines in settings where individuals are exposed to visible signs of rule violations by others, like graffiti on a wall with a 'no graffiti' board (Keizer et al., 2008).

Individual difference approaches argue that independently of the specific institutional context or situation they are in, an individual will consistently cooperate or defect, depending on his or her individual predispositions or personality traits. For example, an experimental study showed that in prisoner's dilemma games individuals with a high internal locus of control, high self-monitoring, and high sensation seeking are more likely to act prosocially than individuals scoring low on these personality traits (Boone et al., 1999). Hence, though confronted with the same situational and institutional setting, there is nevertheless a lot of variation between individuals with regard to their inclination to act prosocially.

Future Directions

The past decade has seen a proliferation of research on prosocial behavior, and much progress has been made in

understanding its sociological implications. We see at least three promising domains for future research.

First, a question that so far received comparatively little attention in the different approaches to prosocial behavior concerns the conditions for *sustainable* cooperation. Institutional approaches still produced limited insights into the conditions needed to create stable sanctioning regimes, or how cooperation is sustained when formal and informal monitoring systems are imperfect. Social preference explanations do not specify under what conditions certain preferences become salient, and why they will remain so. Similarly, experimental studies of iterated N-person dilemmas found that cooperation decreases significantly over time (Ledyard, 1995), starting to wane almost from the start. A stronger focus on the sustainability of cooperative relations and prosocial behavior would also have implications for research designs and evidence-based policy making. For example, with the increasing availability of longitudinal network data and the related statistical models for the analysis of network dynamics (Snijders, 2013), more explicit theorizing on the interrelation between changing social contexts and prosocial behavior becomes possible. Similarly, cumulating evidence on the social basis of human rationality provide new challenges but also opportunities for policy makers facing the challenge to design institutions fostering sustainable cooperation in a variety of settings, like organ donation or tax evasion (Thaler and Sunstein, 2008).

Second, with the growing importance of the World Wide Web for almost all domains of social life, more insight is needed into its effects on prosocial behavior. Internet-based technologies have the potential to reduce coordination and monitoring costs to a minimum, thereby taking away some of the major obstacles that hampered the initiation and maintenance of (large-scale) cooperation. Indeed, growing global interconnectedness is thought to have increased the willingness to contribute to the production of public goods, strengthening as it does a cosmopolitan attitude, while weakening the influence of ethnicity, locality, and national identity (Buchan et al., 2009). Nevertheless, very little is known about such secular trends, and to what degree this technological change affected the emergence of new forms of prosocial behavior and joint production, indeed.

Finally, though the science of cooperation made tremendous progress, sociology can certainly benefit from a more active reception of advances in related fields, particularly those focusing on behavioral microfoundations, like social psychology, behavioral economics, and the cognitive neurosciences. But the same holds for the reception of sociological insights by other fields, particularly for those cases in which physiological or neural processes are presented as ultimate 'causes' of prosocial behavior that are insensitive to changes in social contexts. A nice example is the proliferation of studies on the role of the 'cuddle hormone' or 'love drug' oxytocin as an indiscriminate trigger of prosocial motivations in humans. Instead, a careful recent study, which took the social context serious, found that "oxytocin creates intergroup bias because it motivates in-group favoritism and, to a lesser extent, out-group derogation" (De Dreu et al., 2011: 1). As this and other examples show, there is still much to be gained from more dedicated interdisciplinary work on the sociology of prosocial behavior.

Alzheimer's Disease: Behavioral and Social Aspects

Dieter Ferring, Research Unit INSIDE, University of Luxembourg, Walferdange, Luxembourg

This article is a revision of the previous edition article by E. Miller, volume 1, pp. 423–425, © 2001, Elsevier Ltd.

Abstract

This article gives an overview of the behavioral and social aspects associated with Alzheimer's disease (AD). It first offers an outline of the phenomenology and diagnosis of the disease, followed by systematizations, and guidelines to be adopted in the study of psychosocial aspects of AD. These comprise a socioecological viewpoint and a life span developmental perspective underlining the significance of adaptive efforts of both the concerned individual as well as of the family and further significant others. The psychosocial consequences of AD are then described for different stages of the disease elaborating different topics and tasks for individual adaptation.

Introduction

Within the category of neurodegenerative diseases, Alzheimer's disease (AD) takes a prominent role given that an estimated 24 million people worldwide have dementia, the majority of them assumed to have AD (Ballard et al., 2011). Ferri et al. (2005) report that the number of people living with dementia will almost double every 20 years, from worldwide 24.3 million to 42.3 million in 2020 and to 81.1 million in 2040. Based on their Delphi consensus study, the authors estimate that the total number of 4.9 million people suffering from AD in Europe in 2009 will increase to 6.9 million in 2020 and to 9.9 million in 2040.

It comes as no surprise, therefore, that AD has become a 'popular' concept in such a way that the term has already entered everyday language with people using it to explain a wide variety of memory problems or other kinds of non-successful cognitive performance. AD poses a threat to the individual and the society and even though research on this disease has been promoted during the last three decades and several risk factors have been identified, the specific causes of AD and, hence, reliable prevention and treatment remain elusive. A significant aspect of the threat that AD poses to both the individual and the society thus contains uncertainty: neither the individual knows if he or she will be affected nor does society know which impact the disease will have on public expenditures, distribution of resources, and 'resource fairness' between generations.

The reception of AD by the life and social sciences as well as other science disciplines is illustrated by the number of dedicated journals that have appeared during the last decades (including 'Alzheimer's and Dementia – The Journal of the Alzheimer's Association'; 'Alzheimer Disease and Associated Disorders'; 'Alzheimer's Research and Therapy'; 'American Journal of Alzheimer's Disease and Other Dementias'; 'International Journal of Alzheimer's Disease'; 'Journal of Alzheimer's Disease'). In addition to this growing number of journals, one finds specific publications concerning the various aspects associated with AD in high-impact journals of geriatric medicine.

In order to develop a first idea of the behavioral and social aspects that describe the public reception of AD, one may look at the 'World Alzheimer Reports' published since 2009 by Alzheimer Disease International (ADI). ADI represents the international federation of Alzheimer associations around the world combining 80 national associations. Since 2009, this organization has published five reports focusing on different topics associated with the disease. Specifically, the published reports have dealt with the phenomenology of the disease (2009), its economic impact (2010), the possibilities and options of an early diagnosis (2011), the notion of stigma associated with the disease (2012), and long-term care (2013). (All reports can be downloaded at: http://www.alz.co.uk/research/world-report.) Following this, to talk about AD signifies at first an understanding of the phenomena defining the disease. The second notion describes the imminent costs associated with the disease that amounted to US$ 604 billion in 2010; of these 70% appeared in Western Europe and North America (Wimo et al., 2010). Stigma and stereotypes around AD represent an important social aspect of the disease implying different consequences for the affected person and his/her family.

I will address some of these issues in the following starting with a short description of the phenomenology and diagnosis of AD including the options for an early diagnosis since this has consequences for psychosocial effects that the disease will have on all concerned persons. In the second part, I will introduce guiding principles and perspectives that will be helpful to systematize the study of the psychosocial aspects of the disease, and the third part, will focus on the psychosocial aspects by reviewing the effects that the disease has at the personal and social family level.

AD – Phenomenology and Diagnosis

"*Ich habe mich sozusagen selbst verloren* – I lost myself" is an often-cited sentence by Auguste D. – the first person diagnosed with the disease that the world came to know by the name of the psychiatrist and neuropathologist Alois Alzheimer who described this disorder in 1906. The quotation basically describes the loss of self-consciousness and a state of confusion that defines one aspect associated with AD. In 1901, Auguste D. was brought by her husband to the *Institution for the Mentally Ill and for Epileptics* in Frankfurt (Germany) after showing symptoms that are nowadays considered typical for AD. She showed memory loss, delusions, and sleep problems; she also screamed for hours in the middle of the night. Tests performed by

Dr Alzheimer showed further cognitive deficits. (Retrieved at the site of the German Alzheimer Association, May 2014: http://www.deutsche-alzheimer.de/unser-service/archiv-alzheimer-info/auguste-d.html#c767.)

More than 100 years later, the term AD stands for a brain disorder usually starting in late-middle age or old age and including several symptoms such as memory loss, confusion, reduced problem solving and thinking, and changes in language, behavior, and personality. According to the *Diagnostic and Statistical Manual of Mental Disorders Fourth Edition*, AD is defined by multiple cognitive deficits causing significant changes in social or organizational functioning characterized by a gradual onset and continuing cognitive decline. Multiple cognitive deficits comprise memory impairment and at least one or more additional cognitive disturbances (i.e., aphasia, apraxia, agnosia, disturbances in executive functioning). The *International Classification of Diseases-Version 10* (ICD-10) differentiates four forms of 'dementia in Alzheimer's disease' (F00): Dementia in AD with early onset (F00.0), with late onset (F0.01), atypical or mixed type dementia in AD (F00.2), and an unspecified form of the disease (F00.9).

AD is first described as a neurodegenerative disease that affects the central nervous system by continuously destroying neurons and neuronal activity. In particular, the neurodegenerative process involves nerve cells in the brain to stop working by interrupting information transfer between synapses, to lose connections with other nerve cells, and to finally die. Specific for this situation is the presence of amyloid plaques consisting of beta amyloid – a toxic protein peptide – and of neurofibrillary tangles (Brion, 1998). Biochemical processes underlying the production of these proteins have led to the discussion of a genetic component of AD. Here, research has focused on mutations of selected genes on the chromosomes 21, 14, and 1 (Castellano et al., 2011). Moreover, mutations found within the two genes – presenilin-1 and presenilin-2 – may cause early onset AD also by harmfully influencing the processing of beta-amyloid (Haass, 1996).

In 2011, the National Institute on Aging and the Alzheimer's Association elaborated new criteria for the diagnosis of AD. These new criteria differentiate three stages, namely, preclinical AD, mild cognitive impairment (MCI) due to AD, and dementia due to AD (see Jack et al., 2011). In contrast to the categories defined in the ICD-10 comprising mild/early stage, moderate/midstage, or severe/late stage, these recommendations state that AD begins before the mild/early stage implying that specific disease-related changes can be diagnosed even before this stage. Thus, this stage is considered as preclinical, followed by MCI due to AD. The third stage comprises all three stages from mild/early stage to severe/late stage. Mean survival time after diagnosis is estimated between 4 and 8 years in people over 65 years; there is also evidence of people surviving up to 20 years after the diagnosis (see Helzner et al., 2008).

Psychosocial Effects of AD: Adaptation in a Socioecological Context

In order to describe the psychosocial effects that a neurodegenerative disease like AD has on the individual and his or her social environment, one may start with the observation that there are multiple effects on several life domains for all persons involved. A first systemization of these effects starts by distinguishing descriptive levels, and here one may use the socioecological model proposed by Bronfenbrenner (1979) as a heuristic tool. He elaborated this model as description of the developmental contexts in childhood and adolescence but it may also be used to describe the micro- and the macrosystemic interactions that constitute the living context of persons affected by AD.

Bronfenbrenner (1979) places the person at the center of microsystems, which are defined by him as "a pattern of activities, roles, and interpersonal relations experienced by the developing person in a given setting with particular physical and material characteristics" (p. 22). Microsystems comprise the interactions in the family setting and the closer social networks of a person and thus exert a direct influence on the individual. They constitute greater social entities called mesosystems, which are described by the interaction between several microsettings such as family, school, and work. In addition, exosystems constitute settings in which the person does not directly participate but which, nevertheless, have an indirect influence on the individual; such systems comprise, for instance, the place of employment of one's partner and family members, educational institutions of one's children, or the residential background. Changes in these settings will affect a person as well. The macrosystem finally comprises the social, political, and cultural background of a society at a given historical time, and this sets the frame for further influences on the life situation of a person affected by AD.

From this point of view, AD impacts several individual domains of functioning: the affective-motivational, the behavioral, and the cognitive domain. A second differentiation highlights the impact on the social interactions of a person affected with AD at the microlevel, i.e., in his or her partnership, family, and further social networks. This is then followed by the impact that changes in these specific systems will have on the meso- and exolevel. An informal carer, such as a partner or child, may no longer be able to work full time (or at all), they will not be able to participate in former social activities, and finally, informal care has an impact on the whole family system and its relation to settings at the meso- and exolevel, which may then lead to repercussions on the individual and family. The employer may question the efficiency of a family carer, and social partners and networks may minimize the contact. Finally, AD challenges the macrolevel and thus society as well, which is reflected by an ongoing discourse at various public levels. Prominent among these, one finds the sociopolitical debate of meeting the challenges that dementia and neurodegenerative diseases place on society, especially with respect to solutions assuring the financing of individual care in case of dependency. In fact, several European countries have come up with national strategies to deal with AD, and various practices and policies are implemented across Europe with respect to this question. At present, the existence of national Alzheimer's associations in more than 80 countries worldwide underlines the urgency of public debate and the necessity of representing the interests and needs of Alzheimer patients and their families.

A second systematization that is offered here derives from life span developmental theory and captures the notion of

development as a bio-sociocultural coconstruction comprising the influences of biogenetics, culture, and personality dynamics on human behavior. In order to conceptualize human behavior in the context of AD, one has to take into account the complex pattern of epigenetic interactions between personality dynamics and biogenetics in a given cultural context (see Zittoun et al., 2013). In such a view, human behavior is influenced and formed by normative and nonnormative events and tasks that require adaptation across the life span (Boll and Ferring, 2013). Such a perspective includes a focus on the timing and chronology of events challenging the individual. If one takes the diagnosis of AD as a marker event or significant indicator of life change, one can thus differentiate between antecedent, process, and effect variables that describe the process of adaptation to the changed life situation. Persons affected by AD differ in their biographies and, thus, show differing profiles of personal and contextual characteristics prior to the diagnosis. These will shape the effects that AD will have on the person and his or her network and the subsequent process of adaptation.

A third point concerns the concepts of adaptation and coping of the person affected with AD as well as of the family system to the changed life situation. (Here we use the term 'coping' synonymous to the term of adaptation since both capture the meaning of coming to terms with a given life situation involving various criteria of adaptation.) It is a well-known phenomenon in gerontology that individuals facing comparable demands (e.g., multimorbidity, handicaps) may differ greatly in subjective indicators of adaptation (e.g., self-esteem, subjective well-being). The paradox of well-being describes the phenomenon that a 'bad' life situation is judged as good; this is taken as an indicator of the effective use of adaptive processes in old age allowing for a regulation of the self-perception and subjective well-being (see Ferring and Boll, 2010). When considering the effects that AD may have on the individual and family life, one should be aware that comparable levels of demands, impairments, and strain might not result in comparable outcomes. These results will depend on the already mentioned contextual and personal resources that a person and family may rely on, but also on the adaptive processes underlying the regulation of the self and subjective well-being.

Several models specify such processes at the individual level assuming, for instance, that the elderly person may actively select goals, optimize existing capacities, and compensate losses (e.g., Baltes, 1997). The dual process model proposed by Brandtstädter and coworkers (e.g., Brandtstädter and Greve, 1994) supposes – in line with Piaget – that persons in general assimilate experiences into their cognitive schemata thus confirming their view of the self and the world; if this is no longer possible they immunize against self-threatening experiences (e.g., by selective comparisons) or accommodate their cognitive schemata. It goes without saying that all these efforts require a certain level of awareness and cognitive functioning that will be progressively reduced in the context of AD. The conditions for applying these models to the person affected by AD may no longer be given in the course of disease progression, thus challenging at the individual level the conceptual significance of the term adaptation itself.

As a last point, the process of adaptation is, in itself, not only to be conceptualized as an individual adaptive effort but rather as a systemic and historical process in which a concerned person's behaviors (i.e., the diagnosed person as well as the members of his or her social environment) have an impact on one another. One may describe this interplay of adaptive efforts as a type of 'polyadic coping' thus underlining the reciprocity of behavior in social systems.

Psychosocial Effects at the Individual and Family Level

In the following, from a life span developmental perspective, I conceptualize the diagnosis of a life threatening disease as a nonnormative event that confronts the person and his or her family with a series of new tasks that will require adaptation in several domains. A distinction will be made here between the early phases of disease onset and the time course of disease progression and consider phenomena at the individual as well as the family level thereby including involved significant others in the sequence of events.

Onset of AD – A Stage of Insecurity and Emerging Losses

AD is often diagnosed in the mild dementia stage since memory functioning and daily activities are apparently and observably impaired. The diagnosis of AD is considered here to mark the onset of the disease although the indicators of a weakened performance in the cognitive and functional domain certainly are registered, before this 'official' marker, during the pre-dementia stage. The concerned person, the partner, as well as friends and family members may register behavioral changes mostly indicated by weak memory performance and mood- and motivation-related phenomena linked to depression (see Berger et al., 1999). Comparable to other diseases and as has been argued elsewhere (Ferring and Filipp, 2000), one may characterize this stage as 'weakly scripted,' which signifies – in the terminology of cognitive psychology – that the concerned persons have no scripts and, related to this, are lacking the specific behavioral routines to deal with the situation at hand. Moreover, whereas other negative life experiences (e.g., loss of a loved one) are embedded into culturally shaped ways of responding and routines that often facilitate the coping process, the initial diagnosis of AD clearly lacks this external facilitation – there is no 'ritual' or 'normed' response to this.

The time leading to the final diagnosis of AD is often experienced as even more challenging than the diagnosis of other chronic and life threatening diseases. This is due to the already observed and expected damage to cognitive functioning that, in most cases, has led to the diagnosis and that will deprive the concerned person of their capacity to act in a self-responsible way in the long run (see Bourkel et al., 2012). The capacity to make decisions in a self-responsible way comprises the knowledge about the consequences of one's actions as well as the intention to willingly achieve these actions. Self-responsibility in the context of health behavior comprises the responsibility for health self-management even if the causes for the disease may be beyond one's control. With the progression of the disease, a person with AD will become dependent from significant others that will take over in making 'advocatory' decisions concerning his or her life

(see also 'models of helping and coping' according to Brickman et al., 1982).

Sabat (2002) first raised the question of the convergence of awareness of Alzheimer-specific deficits between AD patients and AD researchers and diagnosticians. Moreover, he questioned what this signifies for the epistemological issues involved in social situations where deficits due to AD are assessed. Specifically, he elaborates that by attributing a lack of awareness about one's condition to the person with AD, one may fail to understand "that what the person with AD does or does not do (such as admit to or discuss fully his or her deficits) is itself affected powerfully not only by the organic effects of the disease, but also by (a) the person's reaction to the disease's effects; (b) the behavior and reactions of others; and (c) the reactions of the person with AD to the behavior of others in his or her social world" (p. 281). In this statement, which transcends beyond the organic effects, the author links the persons affected by AD to their social partners and the social situation.

Using this reasoning one may construct a scenario, occurring especially in the early phases of the disease, where both the affected person and his or her social context may be permanently challenged by the question of whether a specific behavior is already indicating a decline that cannot be hindered. Awareness of disease-related changes plays a crucial role here, and high levels of awareness have been related to dysthymia and anxiety of the person with AD (Aalten et al., 2005). Anosognosia is a concept that describes discrepancies in disease awareness between the persons with AD and their social partners (Maki et al., 2012). Recently, van Vliet et al. (2013) reported that intact awareness of the disease was associated with depressive symptoms both in young-onset and late-onset AD. de Boer et al. (2010) conducted interviews with early-stage AD patients, and they reported that "the experiences of the participants appeared less negative than the ideas 'healthy' elderly often have about a life with dementia," thus indicating a more positive evaluation of the disease-related changes.

Within the context of individual adaptation, the potential discrepancy between external views and the views of the AD patients themselves provides us with an additional domain for study. Most models of cognitive adaptation start with the notion that a person perceives an external event, evaluates this event with respect to its significance for individual needs and – depending on this evaluation – initiates coping behavior that may serve problem- and/or emotion-focused goals (e.g., Lazarus and Folkman, 1984). Such a view of goal-directedness presumes a certain 'rationality' underlying individual behavior since the specific behavior will serve a specific need. This assumption is, however, clearly invalid in the situation of a person with AD. Though there is evidence that AD patients may be aware of their situation and it is worsening (van Vliet et al., 2013), it is well established that the capacity for information processing and the regulation of individual attention will be influenced by neurodegenerative processes.

Assuming that attention depends largely on our current state of goals, motives, and needs, a logical question concerns the motives that guide the perceptive structuring of one's environment, as brain function deterioration progresses. Moreover, perception and evaluation both rely on intact memory given that top-down processing plays a significant part in self-regulation allowing us to recognize and predict events and persons. Starting with the reduced capacity of working memory and the progressive impairment in the functioning of semantic (e.g., agnosia, aphasia), procedural (e.g., aphasia), and episodic memory (e.g., inability to recognize formerly well-known persons), it becomes evident that persons with AD are not able to process information in the instrumental and/or rational way necessary for serving individual adaptation. AD thus not only destroys individual information processing and executive functions but also challenges theoretical models of adaptation and the underlying concept of human functioning.

Disease Progression and the Necessity of Care

Caregiving, with all its diverse aspects, represents a central task for the patient's partner and family when the disease progresses. A first and obvious differentiation concerns the role of formal and informal care. Specific cost calculations show, for instance, that there will be considerable challenges to national households due to AD care and that informal care will be necessary to account for this (Wimo et al., 2010). With respect to formal assistance, one may discern between professional home care services, day care units, and nursing homes for meeting the growing care needs of AD patients. Depending on the solutions found in specific national contexts, families will have to decide how they can afford the costs associated with this and – as this is paralleled on the larger scale in political household decisions – responsible persons have to decide where and for whom the family money will be invested. For example, will there be enough money to finance the further education of one's children, and how can this be arranged with the needs of a person who will be in progressive need of care? Here, the notions of 'resource fairness' and intergenerational justice are advanced to describe the underlying question of how to distribute, in a just way, the means available to the family, which certainly will be a distressing task if these means are limited (Ferring, 2010).

Considering the *tasks involved in informal caregiving*, one may start with the notion that the specific literature highlights primarily the stress and strain associated with such tasks for the caregiver and his/her family while the potential gains in such a situation are rarely discussed, if at all (Boll and Ferring, 2013). The caregiver situation and the associated caregiver career certainly represent various demands and challenges where the concerned person – in most cases – cannot rely on specific knowledge or behavioral routines and coping expertise. This concerns not only the person who is identified as the caregiver by the family system and who is, in most cases, female (Di Rosa et al., 2011), but also all other microsystems within this context, including partners, children, siblings, and further kin as well as friends and neighbors. Classification of strain experienced in caregiving starts with the differentiation between primary and secondary stressors (see Boll and Ferring, 2013). The first ones comprise the tasks associated with the concrete tasks of delivering care (see Wilkins et al., 2009). These include *assistance in daily living routines* (e.g., personal hygiene, toilet hygiene, eating, dressing), and in *medical treatment* (e.g., medication, change of dressings and bandages). Further domains comprise *household activities* (e.g., house work, shopping), and dealing with *financial and administrative issues* (e.g.,

health insurance). For the prevention of risky behavior and situations, Alzheimer care also includes the supervision of the AD patient, for example, to prevent the person from running away or to deal effectively with irritable, aggressive behavior. A considerable part of the strain associated with care may also comprise the emotional support to be provided in cases of multiple suffering (Monin and Schulz, 2010). The patient may, for example, experience physical pain, emotional strain, episodes of anxiety and depression, as well as spiritual crises. As these examples illustrate, family carers may face extremely demanding situations, which make adaptability very important.

Primary stressors affect several life domains (e.g., job, leisure time) of carers and thus result in secondary stressors. Dividing one's resources between the person to be cared for and other family members, having to deal with reduced work time or quitting one's job, facing financial shortcomings, and making ends meet are examples of these secondary stressors (Pearlin and Aneshensel, 1994). Primary and secondary stressors add up to the total strain of caregivers. The subjectively experienced strain is, however, not a uniform phenomenon across carers because several factors moderate the impact of these. Research has shown that there is a multitude of tasks associated with caregiving and that there are several moderating factors helping to explain and predict the differing ways persons come to terms with these tasks (for an overview see Pinquart and Sörensen, 2007, 2011).

Moreover, 'coming to terms' can be measured with respect to different criteria of adaptation. One may, for instance, consider indicators of subjective well-being (both cognitive and affective; see Ferring and Boll, 2010), or rely on more objective criteria such as indicators of physical strain (e.g., physical symptoms, numbers of sick days, medication, and life expectancy of caregivers), financial means, or social participation of caregivers. To add even more to the complexity of these findings, coping and adaptation do not take place in a social vacuum but always involve social partners directly or indirectly (i.e., via others) by the different ways a person may cope with caregiving. Specific coping behavior of family members thus always has an impact on the other members within this system (i.e., 'polyadic' coping, see above). In addition, the process of adaptation has to be projected on a time line that covers the growing number of experiences shared by the caregiver and their social networks including the changing tasks associated with disease progression.

This complexity can be systematized by identifying a universal task of individual coping efforts. It is assumed that the *construction of meaning* underlying the diverse experiences that the caregiver and their network undergo constitutes this task. The use of the term 'construction' conveys that this is a process of changing mental representations of the world and the self via accommodative efforts. Meaning construction is thus considered a cognitive effort of self-regulation on the side of the partner and significant others when confronted with a person with AD. Several theoretical ways of conceptualizing meaning in the context of adaptation exist (see Hicks and Routledge, 2013), and here I would like to highlight conceptualizing meaning under a teleological perspective, which involves the construction and identification of goals associated with the experience of care. Identifying goals implies that the specific experiences may serve a function and are thus not meaningless; following such a reasoning, goals may also be considered as gains originating from the experience of caring (Emmons et al., 1998). The assumption builds on theoretical models elaborating that there is a genuine need for the experience of personal control in order to avoid feelings of help and hopelessness (see Ferring and Filipp, 2000). Meta-analytical findings underline this, for instance, by demonstrating that self-efficacy – as opposed to helplessness – differs significantly between caregivers and non-caregivers and that these differences are especially pronounced between dementia caregivers and non-caregivers (Pinquart and Sörensen, 2003).

The Last Stage of the Disease – Accepting Losses

Making meaning of the changed life situation also applies to the last stage of the disease for the family and significant others dealing with the person suffering from AD. This phase marks the severe late stage, which begins 4–10 years after diagnosis, although longer delays have also been reported. During this final stage, AD patients need daily assistance with personal care and experience a decline in physical activities (e.g., unable to sit, rigid muscles, and abnormal reflexes) as well as complete memory loss. Moreover, persons can no longer communicate coherently, are no longer responsive to social interaction, and thus no features of the former personality seem to remain. Patients may reach a vegetative state due to advanced neurodegenerative processes. Death may come from pneumonia, for instance, caused by impaired swallowing that allows food or beverages to enter the lungs and start an infection. Other common causes of death include complications from urinary tract infections and falls. (Retrieved, May 2014, at: http://www.mayoclinic.org/diseases-conditions/alzheimers-disease/in-depth/alzheimers-stages/art-20048448.)

An adult daughter described the apparent loss of personality of her mother and the inability to communicate in end-stage AD as follows: "I don't have a mother anymore. My mother as I knew her has gone – I became aware of this when l looked into her eyes and got no form of any response. There is nobody in there anymore." This statement marks the permanent experience of loss that family members have to cope with when the person with AD reaches a vegetative state. Coping with loss is the central topic of this last stage. These losses are irreversible since the cognitive capacity cannot be reestablished nor can brain degeneration be reversed. The awareness that the disease has progressed and that the person will soon die develops as the changes that indicate the terminal stage are registered. Horowitz (1982) has proposed that coping with traumatic events may be described as a sequence of stages starting with an initial outcry, followed by phases of intrusion and avoidance that may end in the final phase of completion. This process is, in itself, not a linear one but shows oscillations between the stages, and persons may move forward and backward between the specific stages. This model is used here as illustration of individual adaptive efforts that concern the family and other significant others who know the person – now in a state of severe dementia – from the

former shared life. Even at this stage, the interaction with the person with AD will still trigger mental associations and habitual reactions based on a common history on the side of the partner or the children. Nevertheless, the appearance and behavior of the person in a stage of progressed AD can no longer be considered as indicating participation in reciprocal interactions. If one imagines how people rely on the responsiveness of their interaction partners on the one side as well as the routinized habitual behavior guiding social interactions on the other, it becomes evident that the loss of response of the AD patient may represent a strong challenge to individual adaptation.

Moreover, other losses are at hand. Severe dementia may lead informal caregivers to rely more strongly on professional care and one may lose the option of caring. The 'patient' may be admitted to inpatient care and one will lose further opportunities to be close to them. The process of dying, particularly when accompanied by palliative treatment, may lead to further insecurities. The AD patient may experience severe pain and may no longer be able to communicate, which may further increase the family's feelings of insecurity. Finally, death of the person will place new demands on significant others, e.g., mourning and sharing the sentiment of mourning while at the same time trying to achieve a level of daily functioning. Coming to terms with loss means, in our understanding, to integrate these experiences in one's view of the self and the world. The person who is capable of constructing meaning out of the specific experiences in such a way of identifying gains and growth will certainly achieve this goal.

Conclusion

Psychosocial aspects of AD and especially its associated coping demands are comparable to those of other chronic and life threatening diseases; yet there are also aspects, which are disease specific. Decline in cognitive functioning, dramatic changes in motivation and emotion, and bodily decline up to a vegetative state confront the partner, family members, and others with questions for which no routines are available or where available routines may not function. Adapting to these changes and demands is a crucial if not the most crucial question for families and social networks of persons with AD. This statement brings us back to the fundamental dynamics underlying human development. The study of the psychosocial effects of AD is thus a study of the adaptive process with its manifold and multifaceted tasks resulting when a family member is diagnosed with AD. Depending on the outcomes of the adaptive process, differential effects may be expected with respect to the quality of life of persons affected with the disease and their family members. A final word should be mentioned here about the impact that AD will have within the context of an aging society. In addition to the challenge of sustaining public expenditures in various domains, one may also expect a discourse on how to distribute social resources in a 'just' way. People with AD will need advocates who will represent their rights for care in an ever-increasingly competitive society.

Abstract

Evolutionally speaking, the human species appears to have a marked tendency to develop lesions that may ultimately lead to the clinical picture of Alzheimer's disease. Intraneuronal lesions initially consist of variably soluble aggregates of abnormal and hyperphosphorylated tau protein (pretangles) that gradually convert into insoluble fibrillar neuropil threads and neurofibrillary tangles. Extracellular plaque-like deposits of β-amyloid protein develop after the tau pathology and occasionally induce the formation of neuritic plaques. Although the pathological process underlying Alzheimer's disease lasts nearly an entire lifetime, only a small number of individuals ultimately develop the clinical symptoms of Alzheimer's disease.

Alzheimer's disease (AD), first described by the physician Alois Alzheimer in 1906, is an insidious progressive neurodegenerative disorder that only can be detected clinically in its final phase. A definitive diagnosis based on antemortem observations is complicated and often misleading (Montine et al., 2012). A major histopathological criterion of AD, and one that is decisive for its postmortem diagnosis, is the assessment of distinctive alterations within the neuronal cytoskeleton that appear in the form of nonargyrophilic pretangle material (precursor of neurofibrillary lesions that consists of variably soluble aggregates of abnormal tau protein that cannot be degraded by involved nerve cells), argyrophilic neuropil threads (NTs), and neurofibrillary tangles (NFTs) in specific subsets of nerve cells of the human central nervous system (see Section The Intraneuronal Formation of Abnormal Tau Protein). Accompanying pathological alterations that appear later than the aforementioned intraneuronal changes include extracellular deposits of the pathological protein β-amyloid (see Section The Extracellular Deposition of Abnormal β-Amyloid Protein) and the formation of neuritic plaques (see Section The Appearance and Composition of Neuritic Plaques).

The Neurodegenerative Process

The Intraneuronal Formation of Abnormal Tau Protein

Tau is a special protein that is mainly associated with the cytoskeleton of cells. Microtubules are normally stabilized by the tau protein. In a hyperphosphorylated state, abnormal tau loses its binding capacity to microtubules. A turning point in the degenerative process are pathological alterations of the cytoskeleton, a kind of internal moveable scaffolding occurring in every living cell, which result from the formation of an abnormal and hyperphosphorylated tau protein in a few susceptible types of neurons (Goedert et al., 1997; Goedert, 1999; Mandelkow et al., 2007; Alonso et al., 2008; Iqbal et al., 2009). In healthy nerve cells, the protein tau is one of the several specific cellular proteins that is associated with and stabilizes components of the cytoskeleton. The abnormal but variably soluble and nonargyrophilic pretangle material that initially emerges fills the entire nerve cell (Bancher et al., 1989). At first, the cell body and the cellular processes of such neurons hardly deviate from their normal shape. In a series of additional steps, this material aggregates to form argyrophilic and nonbiodegradable filaments: the NTs and NFTs that are the hallmarks of AD. NFTs, which often have a flame or cometlike appearance, gradually fill large portions of the nerve cell body and appear black after staining with special silver techniques (Figure 1(a)) (Braak and Braak, 1991a,b; Trojanowski et al., 1995; Esiri et al., 1997). Nerve cells that contain NFTs can survive for years despite marked cytoskeletal alterations. However, they forfeit many of their functional capacities long before premature cell death occurs. After deterioration and disappearance of the host cell, a cluster of the pathological material remains visible in the surrounding brain tissue as a remnant, or the so-called tombstone tangle where it marks the site of the lost neuron (Figure 1(a)). The fact that tombstone tangles are never observed in the absence of fresh pretangle or neurofibrillary lesions accounts for the absence of spontaneous remission in AD patients. In the course of the illness, all of the involved nerve cells proceed through a pretangle phase before developing the argyrophilic filaments. The potential for reversing the pathological process is most probably at its peak during the pretangle phase. Neurofibrillary changes of the Alzheimer type include stable (insoluble) fibrillary inclusions that mainly consist of abnormal and hyperphosphorylated tau protein and develop in a few susceptible types of nerve cells in the central nervous system of the human brain.

The Extracellular Deposition of Abnormal β-Amyloid Protein

Among the many ingredients of the fluid filling the small space between brain cells (the extracellular space) are soluble proteins of still unknown function. Some of them probably result from processing of a normal component of nerve cell membranes known as the amyloid precursor protein (APP). Under certain conditions and for reasons that are still little understood, abnormal processing of the APP takes place, thereby resulting in the formation of the pathological β-amyloid protein, a hydrophobic self-aggregating peptide (Selkoe, 1994; Beyreuther and Masters, 1997; Esiri et al., 1997). It is unclear whether all of the nerve cell types of the human central nervous system contribute to the production of the abnormal protein to the same degree. Within the extracellular space, the β-amyloid

Figure 1 The hallmark of AD is precipitation of abnormal proteins at both intraneuronal and extracellular cerebral locations. (a) The final intraneuronal tau deposits represent the neurofibrillary alterations of the Alzheimer type and include three distinct kinds of lesions: Strands of abnormal tau protein located within involved nerve cell bodies (neurofibrillary tangles) and within their dendritic processes (neuropil threads), as well as abnormal fibrous material which accumulates in swollen cellular processes of neuritic plaques. Extracellular 'tombstone' tangles mark the sites at which the host nerve cells perished. (b) The plaquelike extracellular deposits are composed chiefly, but not exclusively, of β-amyloid protein. Depending on the texture of the neuropil (i.e., brain tissue consisting of nerve cell and glial cell cellular processes; see Section The Extracellular Deposition of Abnormal β-Amyloid Protein), plaques occur in different sizes and shapes. Most cortical β-amyloid deposits evolve as globular structures with or without a condensed core.

protein eventually builds plaquelike deposits of varying sizes and shapes (Figure 1(b)). Globular forms predominate in the cerebral neocortex and occur preferentially in layers III and V. (Neocortex is a part of the cerebral cortex that is typically formed of six layers. The human cerebral cortex consists chiefly of neocortical regions.) Bandlike formations are seen in layer I of the cortex, whereas layers II, IV, and VI are often spared. In the course of the disease, the number of plaques reaches a maximum; yet, even at their greatest extent, large areas of the brain tissue remain free of these deposits. The β-amyloid plaques develop later in the course of the pathological AD process than the intraneuronal abnormal tau material. In addition, they do not correlate with the severity of the clinical symptoms (mild cognitive impairment (MCI), dementia) associated with AD, although intensive research efforts have been devoted to establishing the existence of such a relationship (Schönheit et al., 2004; Korczyn, 2008; Pimplikar, 2009; Braak et al., 2011).

The Appearance and Composition of Neuritic Plaques

Neuritic plaques consist of aggregations of altered glial cells and swollen cellular processes of nerve cells, which, in part, contain argyrophilic and fibrillary masses of the abnormal tau protein (Figure 1(a)). Taken together, the various types of glial cells in the brain outnumber nerve cells by a ratio of approximately 10 to 1: they are the maintenance and repair forces, so to speak, for the neurons. Deposits of β-amyloid fill the extracellular space within the reaches of neuritic plaques. Neuritic plaques are more patchily distributed than simple β-amyloid deposits and are present at much lower densities. Factors inducing the formation of neuritic plaques and the circumstances accompanying their disappearance from the tissue are currently unknown. Some cortical areas remain devoid of neuritic plaques, whereas others display high densities of these lesions quite early in the disease.

Developmental Sequence of the Lesional Distribution Pattern of the Intraneuronal Cytoskeletal Alterations

The intraneuronal tau lesions develop gradually and nearly bilaterally symmetrically at predisposed sites of the central nervous system. Many neuronal types, cortical areas, and subcortical nuclei remain uninvolved, whereas others undergo severe damage. The pathological process begins in select subcortical nuclei, progresses eventually in a topographically systematic manner throughout the cerebral cortex, and requires nearly a lifetime to reach its full extent. The sequence of the spread is predictable and remarkably consistent across cases (Arnold et al., 1991; Braak and Braak, 1991a, 1997; Fewster et al., 1991). By pinpointing the locations of involved neurons, five stages in the development of nonargyrophilic pretangle material and six stages in the evolution of argyrophilic NTs/NFTs can be differentiated (Braak and Braak, 1991a; Braak et al., 2011).

The relationships between age and the AD-associated cytoskeletal pathology can be studied by staging large numbers of nonselected autopsy brains (Braak and Braak, 1997). (The pathological process progresses in a systematic topographical manner through vulnerable brainstem nuclei and cortical regions with relatively little interindividual differences. Staging allows one to distinguish between different neuropathological stages.) The vast majority of

recently studied cases (i.e., $n = 2322$ of 2332 cases) can be assigned to one of these stages, and Figure 2 illustrates a continuum of the cytoskeletal alterations ranging from the very first pretangle material-containing nerve cell (appearing at subcortical stage a) to the extensive destruction seen in fully developed AD (NFT stage VI) (Braak et al., 2011).

Pretangle Stages (a–c, 1a, 1b)

Figure 2 shows the percentage of cases at the recently described pretangle stages (Braak and Del Tredici, 2011a). The most recent study showed that it was impossible to assign an NFT stage to 342 of the total number of 2332 cases (Braak et al., 2011). The brains of only 10 individuals were entirely devoid of abnormal tau pathology (=0.4% of the total 2332 cases) (Figure 2(a)). Fifty eight cases showed only pretangle material-containing nerve cells in a few particularly susceptible nuclei of the brainstem. These cases are referred to as subcortical pretangle stages a–c and occur preferentially in young persons (Figure 2(b)).

Early pretangle material in the brainstem develops only in projection neurons that generate a long and poorly myelinated

Figure 2 Relative frequency of occurrence of abnormal tau stages in 2332 nonselected autopsy cases. (a) Brains of only a minority of cases show absence of any abnormal tau deposits. (b) Nonargyrophilic and nonfibrillar pretangle material occurs in nerve cells or nerve cell processes of subcortical nuclei that diffusely project to the cerebral cortex (stages a–c pathology). (c) Pretangle material additionally develops either in nerve cell processes (pretangle stage 1a) or in cortical pyramidal cells (pretangle stage 1b) usually within the transentorhinal region. (d–f) Fibrillar and argyrophilic lesions (neuropil threads and neurofibrillary tangles) characterize the cortical neurofibrillary stages I–VI. (d) Stage I–II cases, (e) Stage III–IV cases, (f) Stage V–VI cases.

ascending axon with extensive and diffuse ramifications within the cerebral cortex (e.g., cholinergic basal forebrain nuclei, serotonergic upper raphe nuclei, noradrenergic locus coeruleus) (German et al., 1987; Mesulam et al., 2004; Grinberg et al., 2009). Pretangle stage c cases have pathological cells in more than one of these diffusely projecting nuclei. Abnormal pretangle material is most frequently observed in the locus coeruleus of the pontine tegmentum (Grudzien et al., 2007; Sara, 2009; Braak and Del Tredici, 2011a,b, 2012), and involved cells are confined to this nucleus in pretangle stages a and b (Figure 2(b)). It now appears that the AD process begins in the axon (pretangle stage a) and then goes on to involve the somatodendritic compartment of coeruleus neurons (pretangle stage b). The locus coeruleus is also most probably the site where the AD-associated pathological process in the brain begins (Braak and Del, Tredici 2011a; Braak et al., 2011). Noradrenergic and neuromelanin-containing projection cells comprise the locus coeruleus in the pontine tegmentum of the human brainstem. This nucleus sends diffuse projections to virtually all portions of the central nervous system and modifies functions of the cerebral cortex (cognition, attentional states).

Hence, the earliest cytoskeletal alterations are capable of evolving in brains of otherwise healthy and young individuals (Elobeid et al., 2011). Advanced age is itself not a prerequisite for the development of abnormal tau. Accordingly, the initiation of the pathological process underlying AD is by no means an age-dependent one (Nelson et al., 2011). By incorporating the pretangle stages into the natural history of the tau lesions, the preclinical phase of AD lasts for nearly a lifetime (Figure 2). Thus, the pathological process underlying AD offers a much larger window of opportunity for disease-modifying interventions than previously imagined (Braak and Del Tredici, 2012).

In addition to the subcortical lesions described, 274/2332 cases displayed the presence of pretangle material in the cerebral cortex (Figure 2(c)). Cases with involvement confined to neuronal processes alone in the cortical transentorhinal region are referred to as cortical pretangle stage 1a, whereas in cortical pretangle stage 1b entirely immunoreactive pyramidal cells are seen in the transentorhinal region (Braak et al., 2011), a primate-specific transition zone between the allocortical entorhinal region, on the one hand, and the temporal neocortex, on the other side. This transition zone is particularly well developed in the human brain. It is the first site within the cerebral cortex to become involved in the pathological process underlying AD.

NFT Stages (I–VI)

NFT Stages I and II

In NFT stages I and II (Figure 2(d)), argyrophilic tau lesions are mainly localized within specific projection cells located in small areas of the medial temporal lobe that are important cortical components of the limbic system. Deposition of β-amyloid protein is nearly always absent during development of these initial stages. Bilateral structural preservation of these neurons in the medial temporal lobe is one of the prerequisites for retaining memory and learning capacities. During NFT stage I, vulnerable cortical neurons occupy mainly the transentorhinal region of the temporal lobe (Braak et al., 2011). In some NFT stage I cases, the transentorhinal tau pathology may be confined to no more than a single argyrophilic (Gallyas-positive) pyramidal cell. The negligible to mild neuronal destruction seen in NFT stages I and II still remains below the threshold required for the manifestation of clinical symptoms (see Section NFT Stages (I–VI)). These first two NFT stages are already found in teenagers and increase in frequency steadily up to the sixth decade. Thereafter, they decrease and become replaced by more advanced NFT stages (Figure 2(d)).

Lesions that exist prior to the clinical manifestation of many diseases are generally regarded as prodromes. NFT stages I–II and/or pretangle stages are not detectable by means of currently available diagnostic instruments or tests. Nevertheless, these lesions represent pathological changes because the contention that they are normal requires the problematic definition of a point at which abnormal tau 'normally' converts into 'disease-related' abnormal tau. AD as a clinical entity includes dementia, but the AD-associated pathological process is much longer and includes an extended prodromal (preclinical) phase.

NFT Stages III and IV

Subsequently, the lesions reach the hippocampal formation (NFT stage III) and neocortical areas of the basal temporal lobe that adjoin the transentorhinal region laterally. Thereafter, the process encroaches upon anterior cingulate, insular, and more distant neocortical destinations of the basal temporal lobe (NFT stage IV). NFT stages III–IV begin to occur in the fourth decade and increase thereafter in frequency (Figure 2(e)).

The clinical protocols of many individuals at NFT stages III and IV may make reference to MCI, e.g., difficulties solving simple arithmetical or abstract problems, short-term memory or recall deficits (lapses of the so-called working memory), and the presence of changes in personality ranging from suspiciousness to irascible or aggressive behavior, apathy, withdrawal, and bouts of depression (Albert et al., 2011; Markesbery et al., 2006). Imaging techniques for the clinical detection of pathological tau in the brain are in the earliest phase of development (Fodero-Tavoletti et al., 2011; Jensen et al., 2011), and large autopsy-controlled prospective studies are needed to confirm the reliability of currently used biomarkers, particularly in cases with MCI (Jack et al., 1992, 2010).

NFT Stages V and VI

The tau pathology spreads superolaterally (NFT stage V) and finally reaches the primary neocortical motor and sensory fields (NFT stage VI) (Figure 2(f)) (Braak and Braak, 1991b; Braak et al., 2006). With the widespread devastation of the neocortex, patients present with severe dementia (i.e., severe loss of memory, cognitive faculties, and executive functions). The final NFT stages V and VI correspond to clinically fully developed AD. These persons become incontinent for urine and feces, cannot dress themselves unaided, or recognize persons once familiar to them (spouse, children). With the passage of time, they can no longer walk, sit up, or hold up their head unassisted. Increasing rigidity of the large joints leads to irreversible contractures of the extremities and

immobility. Primitive reflexes normally seen only in infants also reappear in the last clinical phases of the illness (Nelson et al., 2007; Dolan et al., 2010; Reisberg and Franssen, 1999; Reisberg et al., 1999; Sabbagh et al., 2010). The period of time, which elapses between the onset of clinical symptoms and death averages approximately 8 to 9 years (Francis et al., 1999).

The prevalence of AD cases at stages V and VI increases markedly with age (Figure 2(f)) and thereby imposes major socioeconomic burdens on societies with a growing life expectancy. The initial and provisional clinical AD diagnosis is usually made at stage V or VI. At these stages, therapeutic interventions are useless because available antidementia drugs cannot arrest, reverse, or modify the tau pathology (Molnar et al., 2009; Wollen, 2010).

AD and Evolution

The marked proclivity to develop abnormal tau inclusions in predisposed neuronal types appears to be intrinsic to the human brain, inasmuch as 99.6% of the total number of recently examined cases show the presence of AD-associated tau lesions (Figure 2) (Braak et al., 2011). A comparable but remarkably lower propensity for the formation of abnormal tau in similar neuronal types has been reported in a few nonhuman mammalian species (Nelson et al., 1994; Cork et al., 1998; Schultz et al., 2000). However, in these species pretangle material develops only at an advanced age in animals living in captivity and not in the wild.

The proclivity of the human brain to develop abnormal tau probably increased considerably during the last phase of evolution when humans appeared among higher primates. This evolutionary phase was characterized by a remarkable increase in brain volume. The neocortex became more expansive and, at the same time, the allocortical entorhinal region (in macrosmatic mammals chiefly devoted to the processing of olfactory data) underwent reorganization in microsmatic primates. (Allocortex is a part of the cerebral cortex that shows a lamination pattern different from that of the neocortex – that is, fewer or more layers as the six-layered neocortex. Important components of the allocortex are the hippocampal formation, the entorhinal region, and the olfactory bulb.) The entorhinal region lost most of its olfactory functions and established new interconnections to the neocortex via the transentorhinal region, thereby preparing the way for massive indirect neocortical input to the hippocampal formation. (The entorhinal region is a part of the allocortex. In the human brain, the entorhinal region functions as kind of an association cortex for the hippocampal formation. It indirectly receives important information from neocortical regions and transfers these data to the hippocampal formation.) These phylogenetically late events left their mark on late-differentiating neuronal types during ontogenesis (Braak and Del Tredici, 2004). The final step in neuronal differentiation is the production of the myelin sheath around the axon (van der Knaap et al., 1991). A singular feature of neurons that are susceptible to the AD process is that their axons undergo myelination postnatally. Late-maturing oligodendrocytes myelinate large numbers of axons simultaneously and, for this reason, some of these axons may fail to achieve an adequate degree of myelination (Ullén, 2009). Thus, the propensity to produce abnormal tau may be associated with these evolutional brain developments (Bartzokis, 2004; Braak and Braak, 1996; Reisberg et al., 1999). However, they would have had no evolutional significance for the survival and further propagation of the human species because our forebearers, owing to their limited life expectancy, would not have lived long enough to develop cognitive dysfunction or dementia.

American and French Revolutions: Impact on the Social Sciences

John C Torpey, Graduate Center, City University of New York, New York, NY, USA

Abstract

This article surveys the significance of the American and French Revolutions in the modern social sciences. It argues that the French Revolution has historically had a greater impact, except among those political sociologists preoccupied with the question of 'American exceptionalism.' Yet this has changed since the collapse of Soviet Communism, and certain features of the American Revolution and the American experience have come to the fore.

The American Revolution, conventionally dated 1776–83, and the French Revolution that followed it beginning in 1789 have traditionally been regarded as the 'founding' events of political modernity (e.g., Palmer, 1959/1964). The emphasis in these discussions is on the *political* features of modern life – popular sovereignty, constitutionalism, citizenship – as distinct especially from its economic aspects, where the stress would be upon the industrial revolution. The two political revolutions, of which the first very much influenced the second (while French thinkers also had a large impact on their American counterparts), are nonetheless regarded as having rather distinctive characteristics that make them very different both in reality and in perception. While sharing a commitment to what would later become known as universal 'human rights,' the social characteristics of the two 'events' diverged sharply – and this divergence has left a lasting legacy in the social scientific understanding of their significance.

As a result, the American and French Revolutions have had very different 'careers' in social scientific writing. The situation was perhaps best expressed by the political theorist Hannah Arendt, who argued in the early 1960s that, because it failed to address 'the social question' (i.e., the question of social inequality), the American Revolution had been an event of 'little more than local importance' in comparison with its French counterpart, and this despite the fact that the latter had 'ended in disaster' while the former had been 'triumphantly successful' (Arendt, 1963: 56). Arendt argued with some sympathy that revolutions are occasions in human life when the world can be made anew, but this can only happen if they institute the 'constitution of freedom.' As against the legislation of freedom, she insisted, no one can dictate an end to poverty – yet that is precisely what the French Revolution sought to do. Eventually, Arendt argued, Karl Marx would transform 'the Rights of Man into the rights of Sans-Culottes' and revolutions would henceforth be concerned with the social question as much as with the constitution of freedom. All this presaged Arendt's dismissal of the idea of 'the social' – the distinctive arena of study of sociology – which she viewed as a misguided understanding of human arrangements that posed inappropriate constraints on human beings' freedom of action. Drawing always on classical Greek understandings of politics, she insisted that persons should be free to act politically, and that their institutions should be designed to guarantee that freedom; economics, the realm of necessity, could have no part in that realm (Arendt, 1958). The American Revolution was a success, in Arendt's eyes, because it concentrated on the only matter that revolutions can address: the institution of human freedom.

The fact that the American Revolution was perceived as purely a *political* event having no social implications, for better or worse, has had lasting consequences for the way in which the social sciences constructed themselves. For example, the writings of Alexis de Tocqueville ended up largely in political science (*Democracy in America*) and in history (*The Old Regime and the Revolution*), respectively, whereas in fact his work is as deeply sociological in nature as it is possible to imagine. Of course, his views of 'democracy' were not as enthusiastic as many in the post-1960s sociology would have preferred, which helped consign him to other, less 'progressive' disciplines. Meanwhile, Arendt was correct to note that Tocqueville was not really interested in the American Revolution itself; like his follower Weber, he saw the roots of the peculiar American trajectory as lying far back in the European past and as more or less unaffected by the course of the Revolution itself.

Tocqueville had famously been impressed by the 'equality of conditions' (de Tocqueville, 2000) that he claimed to have seen during his visit to the country in the early 1830s. His vision of an egalitarian America has thus long contrasted in social scientific eyes with that of an 'aristocratic' Europe, despite the fact that rates of social mobility have in recent years become greater in social democratic Europe than in the sharply stratified United States of the post-1970s era. Even a century ago, however, the Dutch cultural historian Johan Huizinga scoffed at Tocqueville's image of American egalitarianism, dismissing out of hand his claims about the extent to which economic and racial equality prevailed in American life (Huizinga, 1972: 61, 62). Like other more critical observers, Huizinga found the United States a rather more conservative place than Tocqueville had. This was at least in part because the American Revolution had been – like the Dutch Revolt against the Spanish Habsburgs two centuries earlier – "a conservative revolution – a struggle for the preservation of liberties more than for the conquest of freedom" (Huizinga, 1972: 18). The slaves would presumably have seen it that way as well.

Tocqueville was also struck by the Americans' distinctive 'point of departure,' but this had nothing to do with its revolutionary origins. Instead, the Americans' advantage lay in the fact that they had no feudal regime to combat and to eliminate: "they have arrived at a state of democracy without having to endure a democratic revolution." They had been blessed with

a sort of virgin birth whereby they were 'born equal, instead of becoming so.' This passage, quoted in the frontispiece of Louis Hartz's *Liberal Tradition in America*, defined the terms of the subsequent discussion of 'American exceptionalism' in American social science. "It is not accidental that America[,] which has lacked a feudal tradition[,] has uniquely lacked also a socialist tradition" (Hartz, 1955: 6). Werner Sombart had argued along similar lines in 1905 when he wrote *Why is There No Socialism in America?*, and the influential political sociologist Seymour Martin Lipset would explore the basic problematique throughout his professional career (e.g., 1996).

Tocqueville saw the American Revolution not as a uniquely American event, but as an application of theories largely developed in France: "The Americans seemed merely to apply what our writers had thought of" (1998: 201). In other words, Tocqueville regarded the American Revolution as the fulfillment of French abstractions – ones that in his view would have a very bad outcome in France itself, as we shall see. But the Americans had a way of tempering ideological excesses with the judicious application of political freedom, an institution Tocqueville regarded as woefully underappreciated in his native land. Despite his preoccupation with and durable analysis of the United States, then, it was always really the French Revolution that was more central to his concerns.

Notwithstanding Tocqueville's relative lack of interest in the American Revolution, he was deeply traumatized by the French Revolution. He had good reason for this, as his own father had been thrown in prison by the revolutionaries and, it is said, his father's hair turned white overnight from the shock. Tocqueville regarded the French Revolution as an ongoing catastrophe for France that foretold a future of endless political convulsions that did, in fact, persist at least until the declaration of the Third Republic after the Franco-Prussian War (1870–71). Thereafter, the political upheavals in France tended to come in the context of external events and conflicts, such as the 'strange defeat' by the Nazis in 1940 and the process of decolonization in Algeria. With the notable exception of May 1968 (see Zolberg, 2008), such upheavals have been relatively circumscribed since the end of World War II. Aspects of Tocqueville's analysis of the French Revolution have nonetheless had considerable impact in subsequent social scientific discussion.

Similarly, for Karl Marx, France was the most important actor in the revolutionary drama shaping the modern world; the Germans, by contrast, were daydreamers incapable of acting to bring their political reality up to the standards of the day – which were defined by the French Revolution (Marx, 1978a). As far as Marx was concerned, the Americans were mired in religious superstition – a conclusion he derived chiefly from the writings of Tocqueville and his traveling companion, Gustave de Beaumont, who 'assure us in unison' that "North America is pre-eminently the country of religiosity" (Marx, 1978b: 31).

By contrast, the French Revolution had a profoundly anticlerical thrust. Under the reigning notion of the 'divine right of kings,' the Church had been effectively part of the *ancien régime*; accordingly, anyone who wished to bring down the one was compelled perforce to bring down the other as well. The French Revolution thus left a deep legacy of anticlericalism that has shaped 'progressive' politics ever since. Yet this was a historical coincidence, according to de Tocqueville (1998); the revolutionaries were not antireligious per se. This would become obvious when they sought after toppling the monarchy to create a number of their own religious institutions – the cult of the Supreme Being, a new revolutionary calendar (echoing Islam's recalibration of human time), and the like. Notwithstanding its anticlerical qualities, Tocqueville characterized the French Revolution as 'a religious revolution' because the message of the Revolution was widely understood to be not just for the French alone, but one for all humankind. This universalizing bent of the Revolution was a product of its origins in abstract ideas – the ideas of the Enlightenment, which stressed the corruption of political institutions as well as a post-Christian notion of human perfectibility. A revolution that had to strangle a church to achieve freedom was inspired by quasi-religious notions about a common human dignity.

The situation could not have been more different from that in the United States. There, in Tocqueville's view, religion and freedom marched hand in hand: "Among us [in France], I had seen the spirit of religion and the spirit of freedom almost always move in contrary directions. Here [in the United States] I found them united intimately with one another: they reigned together on the same soil" (de Tocqueville, 2000: 282). Despite the fact that religion "never mixes directly in the government of society," it should be "considered as the first of their political institutions" (2000: 280). This contrast between the American and the Continental experiences would have enduring consequences for the self-conception of the society as well as of the social sciences. In particular, it would in the post-Cold War period animate a reconsideration of the long-dominant theory of 'secularization' that paid more attention to American experience and viewed more skeptically the previously normative status of the French. Henceforth, the theory of secularization would come to have more detractors than defenders, although the rediscovery of religion in social science owed perhaps as much to the terrorist attacks of 11 September 2001 as to a real appreciation of religious motivation in social life (Torpey, 2010).

In contrast to the sober-mindedness of the Americans, Tocqueville argued that the French Revolution was shaped by 'men of letters' – the term 'intellectuals' had to await the Dreyfus Affair of the late nineteenth century – who were utterly innocent of practical politics. Tocqueville's analysis of the reasons for the impractical bent of these thinkers' ideas was straightforwardly sociological: "The very situation of these writers prepared them to like general and abstract theories of government and to trust in them blindly. At the almost infinite distance from practice in which they lived, no experience tempered the ardors of their nature; nothing warned them of the obstacles that existing facts might place before even the most desirable reforms; they did not have any idea of the dangers which always accompany even the most necessary revolutions" (de Tocqueville, 1998: 197). In his critique of the abstract ideas animating the French Revolution, Tocqueville advanced a line of conservative criticism of intellectuals that would resonate through the works of later authors such as Joseph Schumpeter (1942) and the American neoconservatives of the last third of the twentieth century. This perspective took intellectuals to task for the abstractness of their thought and its divorce from practical life. The underlying assumptions are Burkean views about the historical 'rootedness' of ways of life

and their refractoriness vis-à-vis 'social engineering' of a rationalist kind.

The influence of Burke can scarcely be underestimated in later conservative critique, and not only there. In his *Reflections on the Revolution in France*, first published in 1790, Burke (1968) denounced the notion of the 'rights of man' as a will-o'-the-wisp that could not, in fact, be guaranteed other than by a constituted political community. Hannah Arendt (1973) would affirm that view more than 175 years later in the aftermath of World War II, and indeed the problem of enforceability remains a conundrum for the idea of 'human rights' to this day. In his diatribe against the revolution, Burke also articulated a conception of social order that would animate some of the central dichotomies in the modern social sciences: *Gemeinschaft* versus *Gesellschaft*, substantive reason versus instrumental reason, personal loyalty versus interest, etc. Tocqueville, Marx, Weber, and many others shared the view that a society of deeply shared understandings was giving way to one dominated by the 'cold skeleton hands' of rational calculation, and that the French Revolution had helped midwife its birth.

Like Tocqueville himself, his countryman Emile Durkheim had virtually nothing to say about the American Revolution. Yet Durkheim's ideas are unthinkable without the French Revolution, of which he was profoundly an heir. His social thought is shot through with the 'principles of 1789,' and he strongly endorsed both the idea of human rights and a qualified 'individualism' that respects not a self-interested 'egoism' but the shared humanity in every person. Despite the fact that Durkheim would become thought of as the chief proponent of the notion of society as essentially a religious entity, he viewed the new 'religion of humanity' in the following stark terms: "man has become a god for man and … he can no longer create other gods without lying to himself" (Bellah, 1973: 52). Meanwhile, Max Weber said virtually nothing about either the American or the French Revolution, presumably because of his pessimistic view that 'democracy' would be accompanied inevitably by greater bureaucratization – even if the extent of bureaucratization might vary in the European and American contexts due to their divergent historical trajectories (see Weber, 1946). Insofar as Weber discussed either upheaval, it is only the French that gets passing mention. As one might see in his discussion of 'Politics as a Vocation,' Weber tended to regard (modern) revolutions as romantic, sterile excitations that fail to measure up to the 'demands of the day.'

Because of the relative marginality of the American experience in European and radical thought, the French revolutionary trajectory and its Enlightenment presuppositions came to be regarded as normative. Even Talcott Parsons (1977), frequently denounced as an uncritical apologist for the American way of life, largely ignored the American Revolution in favor of the French in his discussion of the revolutions that constituted modernity. For Parsons, the revolutions that made the modern world up to the 1970s when he wrote were the democratic, the industrial, and the educational. Together these major social developments comprised the elements of modern citizenship heralded above all by the French Revolution, which, Parsons argued, enshrined equality as a central principle of modern life. In an economy that generates economic inequality, however, equality could only be achieved in a qualified way, through the institution of citizenship. As dissected by the British sociologist T.H. Marshall shortly after World War II, citizenship comprised three principal elements – civil, political, and social. The 'civil' element corresponds to the idea of equality before the law, a key principle associated with the French Revolution and its abolition of feudalism. Next, the 'political' element was embodied in the right to vote, a right that was, however, only gradually extended to many groups (such as women and blacks) during the course of the nineteenth and twentieth centuries. Finally, the 'social' element was associated with the institutions of education and social welfare provision. Taken together, these aspects of citizenship were intended to insure "a share in the social heritage, which in turn means a claim to be accepted as full members of the society, that is, as citizens" (Marshall, 1965: 76).

In keeping with the broader pattern described here, the American Revolution has played little role in modern theories of revolution. Theda Skocpol (1979) stressed the importance of state breakdown in the 'social revolutions' of the modern world, namely the French, Russian, and Chinese. The American Revolution has not, as a general rule, been deemed to measure up to this standard. Ironically, this lack of interest in the American Revolution on the part of comparative scholars of revolution ignores the fact that at least one of the leading revolutionaries of the twentieth century, Ho Chi Minh, drew inspiration in his "Proclamation of the Independence of the Democratic Republic of Vietnam" from the American Declaration of Independence as well as the French Declaration of the Rights of Man.

In contrast, those interested in the problem of 'American exceptionalism,' i.e., the liberal and nonsocialist bent of American history, the lack of a labor party, etc. have been more interested in the American Revolution. Comparing the postcolonial states of the former British Empire (the United States, Canada, Australia, and South Africa) as well as of Latin America, Louis Hartz (1964) argued that these were 'fragment cultures' with a relatively muted sense of class antagonism born of the lack of a settled aristocracy against which to rebel. Yet Lipset argued in his comparative study of the United States and Canada (1990: 9–13) that the American Revolution had been a true revolution, cutting off the fledgling United States from the aristocratic traditions and antagonisms characteristic of the mother country and sending proportionately far more loyalist emigres to Canada than fled revolutionary France. The result, according to Lipset, was the creation of a distinctive political culture with similarities to but also notable divergences from other former British possessions.

Nonetheless, as Arendt had argued, the American Revolution until recently remained a matter of marginal significance to sociologists and revolutionaries, if not necessarily to political scientists and historians, and was long trumped by the French Revolution and its legacy. Insofar as the modern social sciences have inherited a 'progressive' cast from their nineteenth-century progenitors, they have tended to regard religion as superstition or worse, or to simply ignore it as a source of idolatry and mischief. This misunderstanding was based in part on the neglect of the American version of modernization, misconstrued the place of religion in the modern world, and helped lead to deep blind spots in the social sciences with regard to the trajectory of modern history. The worldwide religious resurgence identified in many quarters since the

Iranian revolution of 1979 was only the most important development that fell off the radar of the secular social sciences as a result of the processes Tocqueville had analyzed in his comparison of the French and American trajectories.

Things have changed in this regard since the late twentieth century, when the prominent French historian François Furet declared the French Revolution to be 'over' (1981: 1). This was a matter of some moment, "for the French revolution is not only the Republic. It is also an unlimited promise of equality and a special form of change. One only has to see in it not a national institution but a matrix of universal history, in order to recapture its dynamic force and its fascinating appeal" (Furet, 1981: 5). As Furet had foreseen, this 'special form of change' was disappearing from the historical stage. Soon thereafter, with the collapse of Soviet-style communism, the American Revolution and its legacy came dramatically to the fore, nullifying Hannah Arendt's earlier judgment of its relative obscurity. Furet (1999) would write the autopsy of the successor revolutions inspired by the French, and German social philosopher Jürgen Habermas declared after the fall of the Berlin Wall that the Eastern Europeans were undergoing 'catching-up revolutions' that drew much of their inspiration from the American constitutional experiment. Rather than seeking to 'reinvent the wheel' when it came to constructing new political institutions, the architects of the new regimes (other than in East Germany) were inclined simply to turn to the West for models that were thought tried and true.

In recent years, the Haitian Revolution (starting 1791) has been added to the 'founding revolutions of the modern age' by scholars who regard the focus on the United States and France as 'Eurocentric' or racist in character, or as simply missing one of the chief developments of the period. Notwithstanding the fact that the Haitian Revolution was the greatest slave rebellion in world history and the only one to result in the creation of a state, the subsequent unhappy experience of Haiti – long the poorest country in the Western hemisphere – has not helped cement its status as part of the 'age of the democratic revolution,' however deserved this might otherwise be (see Dubois, 2012).

Taking the American and French revolutionary experiences as paradigmatic, the British sociologist of religion David Martin (1990) has suggestively framed the current period as a contest between the 'trajectory of 1776' and the 'trajectory of 1789.' By this he means a struggle between voluntary religion and its sociological correlates – antistatism, religious pluralism and tolerance, and a stress on personal initiative – and the successor-states of old regimes with established religions and *their* correlates – statism, anticlericalism, and secularism. There would seem to be much to this diagnosis if one considers the contemporary encounter between top-down, statist versions of rule in, say, China, and the efflorescence of voluntaristic Protestantism around the world, particularly in Latin America, Africa, and Asia (including within China itself).

Whether the American Revolution and its antistatist, voluntarist thrust remains the dominant force in the world is now a matter of much debate. As the 'sole remaining superpower,' the United States came to be widely viewed in the post-Cold War period as an imperial hegemon whose military superiority made it unchallengeable – the new Rome. In the aftermath of the terrorist attacks of 11 September 2001, the Bush administration's military adventures in Iraq and Afghanistan inflamed world public opinion against American policies. Since the economic crisis of 2008, brought on by rampant financial speculation and unfunded military expenditures arising from those wars, the United States appears increasingly constrained by debt and dysfunctional political institutions.

Still, whereas in earlier times, evangelical Protestantism in Latin America was sometimes seen as part of a larger, pro-American plot (Martin, 1990), in the meantime it has made very substantial inroads, such that some 25% of Brazilians now identify themselves as evangelicals in a country once almost uniformly Roman Catholic. Similar trends are afoot elsewhere in the poorer parts of the world (Martin, 2002), suggesting that the American style of religion, at least, is making a stealth invasion of many parts of the world. As compared to the lack of government services so frequently encountered in poorer countries, the self-help mode typically associated with the American experience – also important in countries where Islamists have had a prominent role in public life (e.g., Lebanon, Palestine, Turkey, Egypt, etc.) – has had considerable appeal. While state-led development produced an 'Asian miracle' among the 'four Asian tigers' (South Korea, Taiwan, Singapore, and Hong Kong), it is not clear that this sort of growth can be replicated elsewhere. Instead, the so-called Islamic Calvinists are rejuvenating both the economy and the religion of Turkey.

The changes that have taken place in the world since Furet declared the French Revolution 'over' have gradually led to a transformed view of the two 'founding' revolutions of the modern world, or at least of the characteristic aspects of each. Religion is back on the social scientific agenda, even if this had a great deal to do with the shock of '9/11.' The modern social sciences have been profoundly shaped by the perception of the French Revolution as the dominant political event in the creation of the modern world. Yet the events of the past 25 years have given new luster to features of the American Revolution that often seemed less substantial in comparison to the high drama of the French, and this is increasingly affecting the way social scientists think about the world in which we live.

The American Conservative Movement

Ann M Horwitz, University of Maryland, College Park, MD, USA

Abstract

Initially an intellectual tradition stemming from the late 1700s, conservatism in America has grown into a veritable social movement, comprising a complex network of activists, elected officials, lobbying groups, financial backers, and media outlets. This article traces American conservatism from its roots in the intellectual realm to its present-day significance as a social movement and political force. It describes the three main strands of conservative thought – traditionalism, libertarianism, and anticommunism – citing the major thinkers within each strand. To illustrate its development into a social movement, the article presents four watershed moments for American conservatism – Barry Goldwater's 1964 presidential campaign, Ronald Reagan's presidency, the 1994 Republican takeover of Congress, and most recently, the advent of the Tea Party in 2009.

Introduction

Conservatism is one of America's great political traditions, whose origin stretches back to the reaction to the Enlightenment (Mannheim, 1986). Some of its fundamental principles comprise an integral part of American governance and inform the country's legal and economic systems, and how young Americans are prepared for citizenship in a democracy. Conservatism – a "tendency to preserve what is established" (Nisbet, 1952: p. 167) – has played, and continues to play, a formative role in American society both on a macrolevel (e.g., the promotion of free market capitalism) and on a more microlevel (e.g., the individual's right to bear arms). The conservative preference for limited government is one of the most enduring political themes in the nation's history (Nash, 1976). Given its vital place in the American fabric, inquiring into the nature and dynamics of American conservatism is an important academic endeavor.

With roots in the intellectual realm (Nash, 1976), starting with the reaction to the Enlightenment, American conservatism has evolved since Barry Goldwater's 1964 presidential campaign into a true social movement. Its adherents have succeeded in establishing a sphere of influence within the formal political structure (i.e., the Republican Party), and have been successful in mobilizing resources to further conservative aims (Bjerre-Poulsen, 2002). The time of this writing, in 2014, is an opportune one for examining American conservatism as the United States is embroiled in one of its most politically polarized eras in memory. The country has still not recovered from the economic crisis of 2008, and the two major political parties, of course, express quite different ideas about how to solve the problem. With power in Congress split – a Republican-controlled House and a Democratic-controlled Senate – compromise has been elusive. Multiple media spectacles over the budget and the debt ceiling have come and gone, and in October 2013, the federal government shut down for 16 days (Dockterman, 2013). In late 2013, President Obama described the current mode of American politics as "lurching from crisis to crisis to crisis" (Taintor, 2013).

Part of this impasse may be due to increased polarization between liberals and conservatives (see Abramowitz and Saunders, 2008; DiMaggio et al., 1996; Evans, 2003; Zschirnt, 2011). Some scholars, however, argue that the more consequential schism is the widening gap between moderate Republicans and more hard-line conservatives (see Barreto et al., 2011; Boykoff and Laschever, 2011; Maxwell and Parent, 2012). For these researchers, the advent of the Tea Party in the wake of Barack Obama's election in 2008 sparked this divide and heralded a resurgence of conservative activism that represents fertile ground for social scientists' inquiries (Perrin et al., 2011; Skocpol and Williamson, 2012; Zernike, 2010).

This article divides the American conservative movement into two spheres: conservatism as an intellectual movement and conservatism as a social movement. It presents the intellectual side of the movement and its three major strands: traditionalism, libertarianism, and anticommunism. It then transitions into an exploration of four watershed moments of the movement in the twentieth century, which gave rise to an activist social conservatism: Barry Goldwater's 1964 presidential campaign, Ronald Reagan's presidency, the Republican takeover of Congress in 1994, and the present-day emergence of the Tea Party.

Conservatism as an Intellectual Movement

An initial question is, 'What exactly are conservatives trying to conserve?' There may not be one single, all-encompassing answer to this question, as the conservative movement is somewhat fragmented (Johnson et al., 1986; Zumbrunnen and Gangl, 2008). This article will explain more about this fragmentation and various factions within American conservatism later, but first, it is useful to establish some of the root principles of conservatism that undergird the movement as a whole.

As Shannon explains, "Conservatism as a distinct political term is [180] years of age, coming into general usage after the Great Reform Act of 1832 in Great Britain. The word meant opposition to reform. In general, conservatives wish to preserve present or past values rather than to create or adopt new ones" (1962: p. 14). Nisbet adds that conservatism is the "disposition and tendency to preserve what is established … tending to maintain existing institutions or views" (1952: p. 167). Within the American context, this orientation translates into a reverence for the Constitution and its enshrinement of private property.

After the American colonies gained independence from Great Britain, "In the absence of a crown and nobility,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64088-6

conservatism has centered around the Constitution and the institution of private property" (Shannon, 1962: p. 13). For conservatives, the view of the Constitution as a 'compact' is central: "The nation [is] a union of States, sovereign States, whose powers were confirmed by the Tenth Amendment" (Nash, 1976: pp. 200–201; see also Adams, 1984). The emphasis on states' rights is important because it showcases one of American conservatism's key tenets, namely, a preference for limited central government. This principle is articulated passionately by Barry Goldwater (discussed below): "The founding fathers had a reason for endorsing the principle of limited government … Throughout history, government has proved to be the chief instrument for thwarting man's liberty. Government represents power in the hands of some men to control and regulate the lives of other men" (Goldwater, 2003: pp. 214–215). Conservatives favor a relatively strict interpretation of the Constitution, as they distrust judges or other agents of government who might extrapolate from the document liberties for the government that the framers did not intend it to have; such abiding distrust of government is central to conservatism (Nock, 2003).

Conservatives do see a role for government. Its purpose is to safeguard individual rights, specifically the right to private property (Buckley, 2003; Smith, 2007; Weaver, 2009). As Smith explains, "Government responsibilities should be limited to defining and protecting property rights, enforcing contracts, upholding law and order, and correcting for monopoly power and other market imperfections" (2007: p. 101). Buckley adds, "It is the job of centralized government (in peace-time) to protect its citizens' lives, liberty, and property" (2003: p. 203). To conservatives, any conception of the role of government that goes beyond these provisions is a misreading of the Constitution and a perversion of the framers' intent.

Returning to Shannon's assertion that conservatism "wish [es] to preserve present or past values rather than to create or adopt new ones," American conservatives' reverence for the Constitution is interesting in light of the fact that that very document was, in many ways, a radical break from the past (1962: p. 14). In response, a number of conservative thinkers argue that the American Revolution and the Constitution were, in fact, a conservative reaction to a British regime that attempted to impose a nontraditional order (see Kirk, 2003). For American conservatives, in any case, there is something exceptional in the Constitution that is worth preserving (it should be noted that the idea of American exceptionalism was introduced by the Frenchman Alexis de Tocqueville; see Lipset, 1988). To them, the document's reining in of government and privileging of individual property rights separates the United States from other democracies.

Although the principles of constitutional fealty and respect for private property rights underlie the conservative intellectual tradition writ large, that tradition is not a unitary one. Three separate strands of thought comprise the conservative intellectual movement in America: traditionalism, libertarianism, and anticommunism (Schneider, 2003).

Traditionalism

An abiding faith in the exceptionalism of the Constitution notwithstanding, the traditionalist strand of the conservative intellectual movement takes a number of its cues from European thinkers, most notably Edmund Burke (Nash, 1976). Burke's famous *Reflections on the Revolution in France* mounted a frontal assault on what he saw as the corrupting influences of rationalism and liberalism embodied in the French Revolution (Mannheim, 1986). The Burkean mantle was assumed by Russell Kirk, perhaps the most influential American traditionalist thinker.

As Kirk explains, traditionalism posits that there is an absolute moral order, primordial, that must be preserved. Traditionalism eschews any type of moral relativism. "The essence of [conservatism] is preservation of the ancient moral traditions of humanity. Conservatives respect the wisdom of their ancestors … A divine intent rules society as well as conscience, forging an eternal chain of right and duty which links great and obscure, living and dead" (Kirk, 2003: p. 110). In defense of this moral order, traditionalism is inherently reactive and counterrevolutionary, 'Clinging to old ways' (Mannheim, 1986: p. 83).

Importantly, traditionalists do not see government as the ideal guarantor of the traditional moral order's survival. Rather, they focus on nongovernmental institutions such as the family, the religious community, or even an aristocratic order (per Burke) as the appropriate guardians of ancient tradition and order (Schneider, 2003). In terms of contemporary conservative activism, these tenets have found voice in the rhetoric of 'family values' religious conservatives (see Peele, 1984).

Although traditionalism is an intellectual philosophy that romanticizes an ancient past, and conceives of present and past generations as bound together in something of a collective, it is unmistakably conservative in its defense of property rights: "Property and freedom are inseparably connected … Separate property from private possession, and liberty is erased" (Kirk, 2003: p. 111). Despite this clear endorsement of individual property rights, traditionalism concerns itself more with moral order than with economic mores. That distinction separates traditionalism with the next intellectual strand of the conservative movement: libertarianism.

Libertarianism

Aside from support for limited government and for private property rights, traditionalism and libertarianism share little in common. In fact, in some ways, libertarians directly repudiate traditionalists' worship of the past. Where traditionalists mistrust the Enlightenment's privileging of reason, libertarians exalt it. "Liberty … is our thesis; reason shall be our method. Only reason can build a valid and consistent ideology, and only reason can strip unsparingly the veil of custom and habit and myth from dominant ideas and institutions and hold them up to the harsh light of truth" (Left and Right, 2003: p. 251). In traditionalism, libertarians see an overreliance on authority (not necessarily only government authority, but perhaps church authority), and a misplaced focus on moral control over individual autonomy: "Unmodified traditionalism, stressing virtue and order in disregard of the ontological and social status of the freedom of the individual person, tend[s] dangerously toward an authoritarianism wrong in itself" (Meyer, 2003a: p. 259). This disagreement with traditionalists

leads some libertarians to reject the conservative label for themselves (see Hayek, 2003).

While much philosophical distance exists between traditionalism and libertarianism vis-à-vis their perspectives and emphases, the latter's preoccupation with limited government and free markets leads most scholars to include libertarianism under the umbrella of the American conservative intellectual movement (Nash, 1976; Schneider, 2003). It is worth noting, however, that whereas traditional conservatism is associated with counterrevolution and counterreformism, a number of libertarians embrace a vision of themselves as 'radicals': "The genuine libertarian … is, in all senses of the word, an 'abolitionist'; he would, if he could, abolish instantaneously all invasions of liberty: whether it be, in the original coining of the term, slavery, or it be the manifold other instances of State oppression" (Rothbard, 2003a: p. 256). Indeed, this has led some conservatives to caution that "untrammeled libertarianism … tends as directly to anarchy and nihilism as unchecked traditionalism tends to authoritarianism" (Meyer, 2003b: p. 259).

In response to that criticism, Rothbard defines libertarianism as a perspective that "emphasiz[es] the importance of the individual, of his freedom of will, of natural rights and private property," that in no way precludes religious beliefs, and that most certainly encompasses moral principles (2003b: p. 266). This debate between Rothbard and Meyer points to the idea of conservative 'fusionism,' which the literature treats not as a true strand of the conservative intellectual movement, but as something of a substrand within it (Adler, 2004; Nash, 1976). Frank Meyer is considered the father of conservative fusionism, an attempt to marry traditionalism and libertarianism in some coherent way. In his mind, the fusionist school of thought could be the unique contribution of American conservative intellectuals to the field: "It is my aim to make this demonstration, to vindicate on theoretical grounds the native belief of American conservatives that freedom as a prime criterion in the political and social sphere is not alien to the conservative view of man's nature and destiny" (2003a: p. 174). Ultimately, "While concerned with maintenance of an objective moral order and the pursuit of virtue in the individual, Meyer argued that the freedom of the person is the central and primary end of political society" (Adler, 2004: p. 51). In the end, the fusionist label has not endured as much as the libertarian label. Libertarianism, indeed, has a robust place within the conservative intellectual movement.

Before ending the discussion of libertarianism, there is a brief mention of free markets, as this topic sharply separates libertarianism from traditionalism. One of the central libertarian tracts, F.A. Hayek's *The Road to Serfdom* (1944), posits the importance of free enterprise and economic competition to ensuring individual freedom and liberty. Another libertarian standard bearer, Milton Friedman, argues in *Capitalism and Freedom* that political liberty cannot be obtained without economic liberty (1982; see also Smith, 2007).

In short, free market ideology is inseparable from libertarianism. Arguments like Hayek's and Friedman's are often cast – implicitly or explicitly – against alternative economic arrangements. For example, both men wrote during the cold war, when free markets vs central planning was a quite salient political issue. This context brings us to the third, and final, strand of the conservative intellectual movement: anticommunism.

Anticommunism

Although fusionism, as discussed above, comprises an uneasy, tenuous marriage of traditionalists and libertarians, it turns out that the threat of communism had a significant impact on merging the two strands, at least temporarily. Because it "destroyed traditional social order – family, religion, and community – and established the State, under the banner of the communist party, as the final arbiter of all decisions affecting individuals," communism presented a mortal threat in the eyes of both traditionalists and libertarians, giving them a common enemy (Schneider, 2003: p. 131).

According to Nash (1976), conservative intellectuals' responses to communism touched both on perceived threats from abroad (e.g., the policy of Soviet containment) and threats from within (e.g., McCarthyism) (see also Anderson et al., 1965). Perhaps the most notable aspect of the anticommunist intellectual strand is that a number of its central figures were themselves "ex-communists [who] proved their disenchantment with 'the god that failed' by dedicating themselves wholeheartedly to expose the tyranny and evil of communist regimes" (Schneider, 2003: p. 132).

At present, although the cold war is over, the intellectual impulses of anticommunism remain alive within the conservative movement. Indeed, Schneider dubs the same excommunist thinkers who were active in the strand the first generation of 'neoconservatives' (Schneider, 2003: p. 132). Their support of strong national defense and interventionist foreign policy is evident today in the neoconservative faction of the movement.

William F. Buckley, Jr.

A number of key intellectual figures in conservatism have been introduced in the preceding pages. It is worthwhile to touch briefly on the work of at least one other, William F. Buckley, Jr., who founded *National Review* in 1955. The publication remains one of the most influential clearinghouses for conservative thought to this day. Buckley employed and published conservative thinkers from across the spectrum, not necessarily achieving intellectual fusion à la Meyer, but certainly promoting a wider readership among conservatives. It is difficult to overstate the magazine's – and, by extension, Buckley's – contribution to American conservatism (Hart, 2005). "If *National Review* (or something like it), had not been founded, there would probably have been no cohesive intellectual force on the Right in the 1960s and 1970s" (Nash, 1976: p. 153). Incidentally, it was during that very same era that conservatism as a veritable social movement emerged.

Conservatism as a Social Movement

The midtwentieth century saw the transition of American conservatism from an intellectual movement to a social

movement. Where before there had been thinkers and writers, now there were demonstrators and activists. Of course, it would be simplistic to say that the two are mutually exclusive, and that there were no conservative activists prior to the 1960s. Even so, the literature shows a clear shift in that decade toward conservative political activism (Himmelstein, 1990; Pierson and Skocpol, 2007). Four watershed moments for 'mobilizing resentment' toward government power (Hardisty, 1999; see also Crawford, 1980) are evident from the literature: the 1964 presidential campaign of Barry Goldwater, Ronald Reagan's presidency, the Republican takeover of Congress in 1994, and the emergence of the Tea Party in 2009.

Goldwater 1964

Barry Goldwater was a senator from Arizona when he won the Republican nomination for president in 1964. At the time, the post–Eisenhower Republican Party establishment was moderate and seemed unconcerned about overreaches of government power (Andrew, 1997; Bjerre-Poulsen, 2002). This establishment was shocked when Goldwater easily beat New York Governor Nelson Rockefeller for the nomination. Goldwater was an unabashed conservative, directly attacking the notion that government power was an effective mechanism for solving social problems (Middendorf, 2006). Although he went on to be roundly defeated by Lyndon Johnson in the general election, Goldwater's candidacy mobilized passionate support among swaths of voters. A "Republican in the new Western mode, he appealed to voters who resented the intrusion of big government, especially the federal government, into their personal and economic lives" (Pierson and Skocpol, 2007: p. 96). Moreover, Goldwater opposed federal desegregation efforts, which won him support among many voters in Southern states that had previously been Democratic strongholds (Pierson and Skocpol, 2007: p. 96).

Goldwater was also effective at mobilizing young voters. While much of the scholarship on young activists in the 1960s focuses on the left-wing Students for a Democratic Society, the conservative Young Americans for Freedom (YAF) was a major movement in its own right. Although YAF predated Goldwater's nomination, his campaign galvanized young conservatives in an unprecedented way. "Through Goldwater thousands of youth entered politics. The campaign transformed the uninitiated into activists and united traditionalists and libertarians in common cause" (Klatch, 1999: p. 84). Although he did not win the general election, scholars credit Goldwater with injecting a strong conservative strain into the Republican Party (Andrew, 1997; Shermer, 2013). This development manifested its significance over time, its political force becoming strikingly evident when another conservative, Ronald Reagan, ran for president, and won.

The Reagan Era

The conservative writer George Will said, "Goldwater won the election of 1964. It just took 16 years to count the votes" (see Middendorf, 2006). This statement reflects the view that Ronald Reagan, who was first elected to the presidency in 1980, was the second coming of Barry Goldwater. Such writers argued that Reagan's candidacy reinvigorated the same voters who had been energized in 1964:

> They were white lower to middle strata voters who switched to the Republican Party on the basis of a profound "social conservatism"—manifested in opposition to abortion and the Equal Rights Amendment and in general concern over the decay of morality, family, and religion. These voters were more religious than the average American and more likely to be alienated from and angry at a federal government that they viewed as the source of secular, liberal values and programs.
>
> Himmelstein and McRae, 1984: p. 592

It is certainly true that Reagan was a conservative; in fact, Schoenwald credits him with embodying a fusion of anti-communism, traditionalism, and libertarianism 'in his own person,' which was not an easy feat for a candidate who began his adult life as a New Deal Democrat (2001: p. 197). His electoral success marked an important moment for the conservative social movement, as it "brought national attention to a new political phenomenon, often labeled 'The New Right': a network of right-wing political organizations and single-issue groups committed to the creation of a conservative 'counterestablishment' that could outdo liberals in grassroots organization, lobbying, fund-raising, and self-promotion" (Bjerre-Poulsen, 1991: pp. 152–153; see also Jacobs, 2006; Lowndes, 2008).

To what extent the presence of a charismatic standard bearer like Reagan at its center contributed to its success is not possible to say, but there are some indicators that the New Right did manage to pull together disparate strands of conservatism. For example, both moderate and ultraconservatives in the business community came together during the Reagan era (Jenkins and Eckert, 2000). Conservative Protestants were brought into the fold and played an integral role in conservative activism (Peele, 1984; Woodberry and Smith, 1998). In terms of attitudes and public opinion, conservative self-identification increased in the 1980s, including among young voters (McBroom and Reed, 1990; Miller, 1992). Additionally, from 1974 to 2012, over the course of many decades as a social movement, conservatives went from having the highest trust in science (relative to liberals and moderates) to having the lowest, indicating the New Right's success in melding fundamentalist religious views into its coalition (Gauchat, 2012).

At the close of Reagan's tenure, though, "Satisfaction with the economic situation in the fall of 1988 was much more important than moral conservatism in [George H.W.] Bush's election win" (Johnson et al., 1991: p. 303). Bill Clinton, the Democrat, would sweep to victory by emphasizing the economy in 1992. A mere 2 years after his election win, though, Clinton would be confronted by a third strong wave of the American conservative movement as Republicans took back control of Congress in the midterm elections of 1994.

The Republican Revolution of 1994

If Bill Clinton's electoral success in 1992 deflated the conservative movement, the effect did not last long. In the lead-up to the 1994 midterm elections, Georgia Congressman Newt

Gingrich introduced the 'Contract with America,' a 10-point platform, which "represented a type of 'conservatism-lite', aimed at electing a conservative Congress, but one which would not depart too far from the vital center of political debate" (Schneider, 2003: p. 397). In the Contract, Gingrich generally shied away from contentious cultural and social issues (welfare and criminal justice system reform being partial exceptions), focusing instead on issues of fiscal policy and national security (Gingrich, 2003). Like Goldwater and Reagan before him, Gingrich appealed to conservatives' distrust of central government and to their notions of economic liberty.

The Contract "not only helped to unify Republican candidates around a sweeping set of policy proposals but also energized some of the party's key constituencies for the fall campaign" (Balz and Brownstein, 1996: p. 37). The Contract had the desired effect. Conservative activists mobilized and voters delivered Republicans a historic victory: "For the first time since 1954, the Republicans captured control of both houses of Congress. Gingrich was speaker of the House and Republicans controlled both houses of Congress the remainder of Clinton's presidency" (Schneider, 2003: p. 397). The next time that the Republican Party would enjoy such a momentous mid-term election would be in 2010, when a new movement faction, the Tea Party, would emerge to galvanize conservative activists.

The Tea Party

In early 2009, Washington, DC, had barely finished removing the tickertape from Barack Obama's inauguration before the Tea Party started making headlines. The opportune moment presented by a new, Democratic president (and one viewed, rightly or wrongly, as particularly liberal) with a majority in both houses of Congress stoked fear and anger among a set of Americans, many of whom had not been politically active before, who wanted to "take [their] country back" (Skocpol and Williamson, 2012). Obama's election not only pointed to social and demographic shifts within the country, but also came at a time of economic trauma.

The circumstances surrounding the change in power in 2009 represented an opening for conservative backlash. The economic collapse of 2008, the bank bailouts that ensued under George W. Bush, and the economic stimulus enacted under Obama, occurring in tandem with major job losses and home foreclosures, roiled the discourse around the country's economic future. Moreover, the electoral success of a Black man signaled, in some Americans' minds, a shift in business as usual in the country's social and political life (Boykoff and Laschever, 2011; Pease, 2010). This unrest provided an opportunity for conservatives to mobilize under the Tea Party banner.

Part of the challenge of studying the Tea Party is that it is amorphous. "By philosophy and design, [the Tea Party] lacks a central leadership structure that coordinates nationwide efforts. Instead, the Tea Party is a far-flung patchwork of organizations, some local and some national, with a related set of issue concerns and positions" (Karpowitz et al., 2011: p. 303). Thus, when discussing the Tea Party, it is necessary to specify whether one is referring to the local activists who attend meetings and protests, the professionalized movement organizations that formulate framing and steward financial resources, the media apparatuses that deliver framed messages and mobilize support, or the conglomeration of all three (Skocpol, 2012).

Despite this definitional ambiguity, scholars have gained an understanding of basic philosophical tenets and political dispositions that unite disparate arms of the movement. Foley identifies three central principles of the movement: limited government, US sovereignty, and constitutional originalism (2012). Ashbee points to evidence of "deep pessimism about the country's economy and its economic future" as a common characteristic of Tea Party activists and sympathizers (2011: p. 157). Additionally, scholars find that those in the Tea Party are joined by "an intense personal and political antipathy to President Obama" (2011: p. 157; see also Jacobson, 2011; Maxwell and Parent, 2012). Incidentally, that antipathy, although it has been a boon to the movement in terms of political opportunity and recruitment, has also saddled it with accusations of inherent racism and xenophobia.

Employing qualitative interviews, content analysis, and quantitative analysis of public opinion data, Barreto et al. conclude that the Tea Party, rather than a popular movement to rein in government overreach and taxation, is a vocal manifestation of the 'paranoid style' of extremist racist, anti-immigrant, homophobic American politics (2011: p. 1). Berlet points to demonization and scapegoating of liberals, people of color, and immigrants, along with conspiracy theories about Obama as a foreign-born Muslim, as hallmarks of Tea Party orthodoxy (2011). Interestingly, while concurring with the portrait of the Tea Party as a racist movement, Enck-Wanzer also faults Obama for not responding with forceful antiracist rhetoric (2011). The arguments put forth by these scholars, though, depict an overt and nefarious racism among Tea Party activists, veiled deliberately behind language of small-government principles. While they find evidence of stereotyped racist beliefs among Tea Party members, Skocpol and Williamson also find evidence of activists within the movement pushing back actively against racists who 'infiltrate' it (2012: p. 69). Courser (2011) and Etzioni (2011) highlight the potentially problematic impulse of scholars to write off the Tea Party as a cadre of racist xenophobes, and Skocpol and Williamson's (2012) work points to the need for further research to tease out the racial rhetoric within the movement and ascertain the degree to which racism in the movement drives its agenda.

Wilson and Burack theorize that the Tea Party is an articulation of the economic and social strands of American conservatism, making it instrumental in uniting conservatives at a moment of political opportunity (2012). Conceived of in this way, the Tea Party may be said to represent a successful conservative fusion (Meyer, 2003a). What is unknown at present is the extent to which the Tea Party will continue to enjoy influence in the political system, a question that may only be answered by observing future election cycles.

Conclusion

As a movement, American conservatism has shown itself to be dynamic and resilient. Even when Republicans have been the minority in Congress and absent in the White House, the principles that define conservatism have held considerable

sway in American politics. In recent memory, free market ideology and deregulatory policies have been the norm even under Democrats (Jimmy Carter, for example, has named deregulation as one of his administration's great accomplishments; see Smith, 2005). Moreover, politicians across the spectrum have invoked a preference for limited government when speaking to the public. No less loyal a Democrat than Bill Clinton proclaimed, in his second inaugural address in 1997, "The era of big government is over," presumably referring to the New Deal regime put in place after the Great Depression. Regardless of the party in power, conservative ideals have coursed strongly through the American political vein.

Even so, some in the present-day political class see great challenges ahead for the conservative movement. With the demographics of the country changing, racial and ethnic minorities make up an increasingly large portion of the electorate. This new reality has led some – both inside and outside of the Republican Party – to believe that conservatives must change their stance on issues like immigration in order to remain politically viable. Additionally, some assert that conservative positions on gay rights and reproductive rights are alienating young voters and women, an untenable trend if Republicans wish to win elections. Compounding the uncertainty over conservatism's future is the current turmoil within the Republican Party. Since the rise of the Tea Party, Republican primary elections at the state and federal level have often become intense battles between hard-line conservatives (often backed by the Tea Party) and more moderate candidates, leaving the victor's image and coffers bruised and sometimes giving the Democratic rival the advantage in the general election.

Despite these obstacles, though, any eulogy for American conservatism is premature. American politics is pendulous, but however it swings, conservative articles of faith are consistently in favor, at least in electoral rhetoric. Examining American conservatism going forward presents the opportunity to observe how the movement navigates a rapidly shifting political and social landscape, and to gauge its success. This endeavor engages the academic concerns of multiple disciplines: political science, economics, sociology, and others. American conservatism, both as an intellectual movement and as a social movement, has a profound impact on the political and social structure of American life. It is a dynamic movement, and it deserves the attention of social scientists.

Abstract

The American Revolution was the first of the Atlantic Revolutions. Having attained a status of advanced development, the American colonies were not prepared to tolerate the imposition of taxes and tighter controls which the mother country desired to impose on them. Ill-judged policies met resistance which escalated and resulted in war. Aided by the French, the Spanish and the Dutch, the Americans won a famous victory. Most innovative was the creation of a republican government, constructed over a period of three months in the summer of 1787.

By 1750, Britain's North American mainland colonies had achieved the objective conditions to operate as independent states. They had clearly identifiable elites and viable economies. They were distinguished by their wealth, political office-holding social class, education, housing, manners and dress. They had recognized centers of political power in colonial capitals where legislative bodies, dominated by committees employing parliamentary procedures that met to conduct colonial affairs. The franchise was wider than in Britain and there were no rotten boroughs. At local level, county and urban elites exercised power through membership of county benches and town meetings which met on a more regular basis and were more inclusive than their British counterparts. The continuing relationship with Britain, according to Jack P. Greene, was voluntary (Greene, 1973: pp. 132–80).

Although attempts to tighten British control over the colonies could be discerned before the outbreak of the French and Indian War (known as the Seven Years War in Britain), the war changed the dynamic between colonies and mother country. Fought on a global scale and supported by unprecedented levels of taxation, it resulted in British victories at the expense of the French and Spanish, especially in North America, doubled the size of the national debt and made Britain the world's leading imperial power. Little wonder, then, that the British government struggled in the aftermath of the war. As Linda Colley observed, the British were confounded "by the problem of having acquired too much power too quickly over too many people" (Colley, 1992: p. 102). Less sympathetic was T.H. Breen who in a withering indictment of the final years of British rule described Lord North and his cabinet colleagues as 'mediocre,' blinded by their "intellectual rigidity … to the possibility of reforming a system that no longer worked" (Breen, 2010: p. 59).

American expectations at the end of the war were high. Viewing the prospect before the colonists, the Reverend Thomas Barnard joyously proclaimed in his sermon before the Governor and Council of Massachusetts, 'the snare is broken and we are escaped,' but instead of reaping the benefits of their new security, the colonists found themselves not only hedged in by restrictions on western expansion but also subject to demands for taxes to relieve the burden on British subjects, tighter controls on the implementation of trade regulations, the creation of a new Board of Customs Commissioners and the expansion of the jurisdiction of admiralty courts which met without juries (Brown, 2000: pp. 76–78). As a consequence of these intrusions into colonial affairs, traditional rights and privileges, guaranteed to the colonists under their earliest charters, came under threat and, despite repeated setbacks, Parliament insisted on the recognition of its supremacy. This was the rock on which the empire floundered.

The Stamp Act of 1765 which imposed direct taxes on legal documents and printed paper marked a turning point in colonial relations and, although the Sugar Act of the previous year gave some inkling of what lay ahead, its application was more limited. The Stamp Act applied to all the American colonies including those in the West Indies. Led by the Virginia House of Burgesses, the tax was denounced as a violation of English liberties. Only the burgesses could tax their constituents because they alone knew what level of taxation the people could bear since they themselves would be subject to it. Taxation by the representatives of the people was "the distinguishing characteristic of British freedom, without which the ancient constitution cannot exist" (Brown, 2000: pp. 99–100). If Virginians led the way in defining the constitutional opposition to the tax, colonial seaports were the scene of popular demonstrations on an unprecedented scale. Building on existing traditions of popular protest, familiar in eighteenth-century Britain and replicated in Massachusetts, they made the position of stamp tax collector untenable rendering the act unworkable. Opposition to the Stamp Act also marked the beginning of intercolonial cooperation.

At the instigation of the Massachusetts House of Representatives, nine colonies sent representatives to a congress in New York which not only reiterated the constitutional opposition to the tax, but devised further tactics to oppose it by threatening to boycott British goods thus forcing British merchants to lobby for the Act's repeal. They also dismissed the charade that, like the majority of the people of Britain, they, the colonists, were 'virtually represented' in the British parliament. But it was not the threat to the British economy, the violence on the streets or the voices of American friends in Parliament that led to the Act's repeal, but rather the change of government in Britain. Repeal, however, was accompanied by a Declaratory Act that claimed the undisputed right of Parliament to legislate for the colonies 'in all cases whatsoever' (Brown, 2000: p. 112).

In 1767, Chancellor of the Exchequer Charles Townshend proposed new and different duties on selected items such as paint, glass, lead, paper, and tea under the guise of trade regulations, the revenue from which could be used to release royal officials from dependence on colonial legislators for their salaries. He also set up a new Board of Customs Commissioners with its headquarters in Boston, an action that boded ill for a region long associated with smuggling. He also expanded the jurisdiction of vice-admiralty courts giving them authority over breaches of the latest government measures. Townshend also addressed the continuing failure of the New York legislature to provide suitable accommodation and adequate subsistence for soldiers stationed there. In the face of continuing colonial resistance, Parliament resurrected an Act passed in the reign Henry the Eighth under which those guilty of treason or suspicion of treason should be tried in England (*Journals of the house of lords* XXXII, p. 210; *Journals of the house of commons* XXXII, p. 186). Once again the Virginia Assembly responded, members not only repeating their claim to the exclusive right of taxation but also denouncing Parliamentary measures intended to carry men to England for trial on treason charges. Among other colonies, only Rhode Island, a corporate colony enjoying a greater degree of independence than most, followed Virginia's example and denounced England's attempt to hold trials without local juries. The Virginia action led to the dissolution of the House of Burgesses whose members reconvened in a nearby location defining their meeting as a 'convention.'

In Boston, a seaport whose trade was in decline and whose economy had not recovered from the postwar depression, customs men became the butt of local wrath, but not being local men, they were less easily intimidated than the stamp tax collectors. Nonetheless, vulnerable to attack from a hostile population, the customs men requested naval protection in the execution of their duties. Matters came to a head in the wake of the seizure of John Hancock's ship *Liberty* in June 1768 and the riot which followed (Archer, 2010: p. 85). Persuaded that the provincial government of Massachusetts was 'cowed by a popular faction, lawlessness, and imminent insurrection,' the new Secretary of State, the Earl of Hillsborough ordered two regiments stationed in Ireland to Boston. In seeking to promote colonial unity, the House of Representatives dispatched a circular letter to other colonial assemblies. Hillsborough demanded that the letter be rescinded and failing that, that Governor Francis Bernard dissolve the legislature, which was done. At the instigation of the Boston town meeting, a convention of towns was called to meet on September 22 to address the grievances of the colony. Attended by 96 towns and eight districts, its statement of grievances was surprisingly mild (Archer, 2010: pp. 75, 91–93, 100). The weakness of Bernard's position had become only too obvious at the time of the Boston Stamp Act riot when he found that there was no one he could call on to disperse the rioters or even turn to for advice (Brown, 2000: pp. 100–103). Convinced that the governor was misrepresenting them to the authorities in England, it was impossible for the members of the House and the governor to reach any sort of compromise. Two thousand troops in all were billeted in Boston. Not only did this military occupation create tensions between the soldiers and the civilian population but it also raised longstanding issues about the dangers associated with standing armies (Archer, 2010: p. 91, 101). Since the prospect of an uprising was far-fetched, the troops were withdrawn but not before five Bostonians had been shot to death.

Relative calm prevailed after the repeal of the Townshend duties until the attack and burning of the government revenue cutter the *Gaspee* in June 1772. Engaged in patrolling the waters off Narragansett Bay, Rhode Island, the commander of the *Gaspee* was a hated figure among local merchants and mariners in this small New England colony, well known for strong ties to smuggling. Governor Joseph Wanton moved slowly to investigate the *Gaspee* affair and was outmaneuvered by Hillsborough who invoked the recent Parliamentary Act 'for the better securing and preserving his Majesty's dockyards, magazines, ships, ammunition and stores' which provided the death penalty for those found guilty of burning the king's ships and authorized suspects to be brought to England for trial. Yet when the Privy Council met, it overruled Hillsborough's initiative and in its place, instituted a commission of inquiry with a view to securing those charged with high treason under the statute of Henry VIII. The New England press had a field day. The commission was likened to the Inquisition and the court to Star Chamber. Intercolonial committees of correspondence sprang up. The high-powered commission failed to secure local cooperation. Little information was forthcoming and none of the perpetrators were identified. There would be no trials for treason in England, at least not yet (York, 1992: pp. 3–21).

When British efforts to implement the Tea Act met with resistance and the cargoes sent to Boston ended up at the bottom of the harbor, the British government saw it as an opportunity to isolate Boston and to restructure the government of Massachusetts which had singularly failed to submit to the government's will. Convinced that Massachusetts was at the heart of the problem in Anglo-American relations, and that Boston was in the hands of a small radical faction, reestablishing control over the province, it was assumed, would restore normality. The Coercive Acts, called by the Americans the Intolerable Acts, closed the port of Boston, remodeled the character of the Council making it subject to nomination by the Governor rather than election by the members of the House, removed the courts of law outside the town's limits and deprived the town meeting of its autonomy (Brown, 2000: pp. 143–146). Not only would the port of Boston remain closed until its citizens compensated the East India Company for the loss of its cargoes, its punishment would serve as a salutary lesson to the other colonies. Once again, the British government miscalculated as other colonies rallied to Boston's cause. The Quebec Act was not part of the punitive measures but its content confirmed colonists in their perception of the British government as bent on crushing the liberties of the colonists. Some measures in the Quebec Act were progressive in that they recognized French civil law and the use of local taxes for the support of the Catholic Church – both anathema to New Englanders – but in extending the boundaries of the province of Quebec southwards, the Act blocked the westward expansion of Virginia and Pennsylvania. In addition, there was no provision for a representative assembly on the grounds that the population of the area was too small. Until the passage of the Coercive Acts and the Quebec Act, there was little that the

British government had done that warranted the label of tyranny but now its response was harsh, costly and ill-advised. Thwarted at almost every turn, the British government failed to recognize just how flimsy was its authority.

Representatives of 12 colonies gathered in Philadelphia for the first Continental Congress in the summer of 1774. On the one hand, it prepared a loyal address to the king and on the other, laid out the rights and privileges of the colonies. It denounced the Coercive Acts and the Quebec Act as unconstitutional 'and most dangerous and destructive of American Rights.' Its policy of nonimportation, nonconsumption, and nonexportation of goods to and from Britain was buttressed by the newly created 'Association' which raised local enforcement to a new level (Brown, 2000: pp. 152–154). The Congress adjourned but was recalled following the confrontation between British troops looking for stockpiles of arms outside Boston and local militia at Lexington and Concord. As news of the engagement spread, the British soldiers struggling back to Boston suffered heavy losses from snipers along the route. As the militia laid siege to Boston, the second Continental Congress, meeting in May 1775, appointed a Virginian, George Washington, as commander-in-chief of the newly designated continental army surrounding Boston. Delegates did not initially seek independence, but with pressure building up in local communities, and the publication of Tom Paine's *Common Sense*, events moved inexorably toward independence. Paine poured scorn on the institution of monarchy and the outmoded connection whereby a continent could be governed by an island. 'There was a time when it was proper, and there was a proper time for it to cease' (Paine, 1960, pp. 34–35). That time had come.

Why the image of Britain had become so toxic by the end of the colonial period lay in the perception of history as a never-ending struggle between power and liberty. Eighteenth- century Britain had been lauded by continental writers for having solved the conundrum through its form of government which in combining the traditional forms of government – monarchy, aristocracy, and democracy – had created an equilibrium in the form of the mixed or as it was also known, balanced constitution, but political ideas in the colonies were shaped not by John Locke but by the radical republicans of the late seventeenth and early eighteenth centuries for whom liberty was always prey to men of power. Its survival required the vigilance of a virtuous people; its enemies were ambitious men with political patronage at their disposal, not to mention standing armies and city mobs. From the colonial view point, Britain had lost its way, its people had lost their virtue, its government was corrupt and liberty was crushed. The attack on the rights of the colonists and breaches of longstanding political values – in particular the raising of taxes without representation - was a violation of fundamental English rights (Bailyn, 1967). The reason why the colonists embraced the ideas of writers such as Trenchard and Gordon was because the logic of their arguments fitted the circumstances of the colonists. Americans had enjoyed the exercise of certain rights and privileges but they were not theirs by right. The British government had never recognized colonial assemblies as colonial parliaments with all the rights and privileges accruing to them as enjoyed by the English original. There had been no revolutionary settlement in the colonies as had occurred in Britain following the Glorious Revolution. Colonial assemblies were dependent on governors to call them into existence and they could dissolve them at will. Yet the position of the colonial governor in reality was weak. Owing his appointment to the British government, he was dependent on the legislature for his income. Real power, despite appearances, did lie with the lower houses of assembly but British policy toward the colonies following the ending of the Seven Years War was predicated on the assumption of colonial subordination. The disjuncture between theory and practice was resolved by revolution (Bailyn, 1968).

The War

In 1763 the colonies of British North America had closer relations with Great Britain than they did with each other, yet within 15 years, the Americans took on the might of the British empire and prevailed. The conflict lasted a bruising eight years at the end of which and following the loss of two British armies, one in the north at Saratoga (1777) and another in the south at Yorktown (1781), and after protracted peace negotiations in Paris, Britain recognized the independence of their former mainland colonies. British assumptions about their military superiority were slow to evaporate, if, in fact, they ever did, though the importance of the American colonies to Britain declined when a colonial rebellion was transformed into a global conflict as France, Spain and the Netherlands entered the war.

British officers did not believe that the Americans would or could fight according to the rules of war and law of nations while the Americans accused the British of failing to observe both conventions. Atrocities occurred on both sides and each sought to hold the other to account. When General Burgoyne wrote to General Gates about the failure of local militia to give quarter when requested in the case of German troops who fell into a trap when they attacked the town of Bennington, Gates poured scorn on Burgoyne's effrontery reminding him that his Indian auxiliaries had murdered the fiancée of one of his own officers in a case which gave the Americans one of their greatest propaganda coups of the entire war (Morgan, 2007: pp. 221–222, 225, 258). Native Americans, despite the efforts of both the British and Americans to recruit them, like the Irish, were perceived as lying outside the law of nations. Pushed, they chose the British side and paid the consequences when the war ended. Governor Dunmore's proclamation offering freedom to slaves and indentured servants who joined British forces in Virginia heaped more opprobrium on Britain's reputation. Small numbers of former slaves found freedom in Nova Scotia and Sierra Leone, but for most, bondage was perpetual. In the southern states, especially the Carolinas and Georgia where prewar social and political tensions were most acute, partisan militias with scores to settle could not be contained within the conventions of the rules of war and law of nations. When the British launched their southern campaign in the mistaken belief that pro-British sentiment in the region was strong, civil war raged. As the British army under Cornwallis fought its way to north, it became trapped in Virginia and for the second time, the British lost an entire army. Two armies were enough.

Almost until the end of the conflict, the British defined the Americans as rebels and therefore traitors subject under the Treason Act of 1696 to gruesome punishment. As late as November 1780, Lt Colonel Balfour, commander-in-chief of British forces in occupied Charleston, described his opponents as 'fighting in the cause of treason and rebellion' (Moultrie, 1968 [1802], p. 145). When Ethan Allen and some of his soldiers fell into British hands in Canada in 1775, he and 33 others were sent to Britain to await an uncertain fate. Badly mistreated and taunted with the prospect of a traitor's death, Allen was finally sent back to New York, then in British hands, from where he escaped making his way home. Officers might be exchanged when men of equal rank were taken prisoner but soldiers and sailors were not so lucky. In reality the British treated the Americans as enemy combatants but there was no formal recognition of their status other than as rebels though carrying captured soldiers to Britain was not repeated. The British government would not negotiate with the American congress.

When the Americans defeated General Burgoyne at Saratoga in October 1777, the Americans acquired a large number of prisoners who became known as the 'Convention army.' As a consequence of the defeat, 5000 or so British and German soldiers spent the remainder of the war in custody in Massachusetts, Maryland, New Jersey, and Virginia, some of whom were hired out as laborers. Those captured by the British following the taking of New York and Charleston were confined in churches and on prison ships which led to reports of ill treatment, starvation, and high mortality. The situation of sailors was different again. In 1777 Parliament adopted an Act 'to empower his Majesty to secure and detain persons charged with, or suspected of, the crime of high treason, committed in any of his Majesty's colonies or plantations in America, or on the high seas, or the crime of piracy' (*Statutes at Large*, 1780: pp. 18–19). The Act allowed British vessels to seize American sailors and carry them to England where they remained for the duration of the war unless they succumbed to British inducements that they enlist in the British navy. Some 3000 sailors were imprisoned in the jails at Old Mill (Plymouth) and Forten (Portsmouth). There were some exchanges of seamen organized by Benjamin Franklin when he was commissioner in Paris but no formal arrangement was concluded. The Americans seldom had enough British seamen in their custody to exchange for the larger number of Americans in British hands. It was only when the Earl of Shelburne formed a new government in 1782, following the fall of the North administration that Americans captured by the British, were finally recognized as prisoners of war.

The American Revolution in Perspective

The American Revolution was the first of the so-called Atlantic Revolutions and while subsequent revolutions in the Atlantic world had links of various kinds to the American – it certainly bankrupted the French – what prompted American patriots to refer to their contest as a revolution is not altogether clear. Though the ghost of Oliver Cromwell was not dead in New England as Alfred Young has demonstrated, it was unlikely to be the English civil war while hopes of reconciliation were still alive (Young, 2006: pp. 156–164). The most obvious model was the Glorious Revolution of 1688 which overthrew the last of the Stuarts, James II, and with him the divine right of kings and the prospect of a return to Catholicism, guaranteed the role of parliament in national affairs and issued the Declaration of Right, a national charter of liberty (Davis, 1990: pp. 9–10). While some clauses in the latter can be found in the Declaration of Independence and the Bill of Rights, what was truly innovative about the American Revolution was the creation of a republican form of government and its ratification by the American people. Republican governments were not new but they were not found in extensive territories such as the United States, and they did not last.

Confederation and Constitution

In 1787 state representatives gathered in Philadelphia to revise America's first constitution, the Articles of Confederation, that had been adopted during the course of the war and ratified by the last of the states in 1781. A weak instrument of central authority and with no income of its own, it had, nonetheless, kept the nation together during the war and the early years of the peace. Its shortcomings became more evident after the war ended when Britain failed to fulfill its obligations under the Treaty of Paris, social order broke down in some states, borders were contested, interstate rivalries threatened economic warfare and the exclusive authority of Congress in Indian affairs was ignored. Yet it was not without its achievements in peacetime–the passage of the Northwest Ordnance excluding slavery from the Northwest Territories was one of them. If the creation of the Federal Constitution was a reaction to the Articles of Confederation, it was also a riposte to state legislatures that had become the dominant force at state level after the collapse of royal government.

But the delegates to the Federal Convention decided against revising the Articles and started over. The new Constitution was to be the supreme law of the land, it created a power superior to that of the state legislatures but it lacked the power to veto state laws though Madison had favored a veto. Dividing power between the executive, legislature and judiciary, the delegates to the Philadelphia convention in the summer of 1787 sought to balance power and liberty while at the same time having to accommodate the special interests which reflected the diverse economic and social character of the regions that made up the United States and without which nothing could be achieved. There was little problem over the framework of the government, the respective branches and the length of terms of service since they were founded on solid republican principles. The problems came with the question of representation in the two legislative bodies, noninterference in the slave trade and commercial legislation. Compromise was the key to success but it was hard won. Democracy played little role in debates in the Convention and then only to be dismissed. The sentiment expressed by Jefferson in his *Notes on the State of Virginia* (1785) when he wrote that an elected despotism was not the government they had fought for, was widely shared by convention delegates. Slavery was not mentioned by name in the Constitution, but the document was shot through with measures that protected it and it was further reinforced by the Bill of Rights.

Wiececk described it as the fairy-tale witch who though not invited to the party, came anyhow and put a curse on the proceedings (Morgan, 2007: p. 146). Most difficult of all to resolve was the question of representation. James Madison who wrote the Virginia plan which formed the basis of early discussions on the shape of the Constitution, favored proportional representation in both houses, but fearing the loss of power, the small states would not budge. Holding out for equal representation in both houses, they won equal representation in the senate, a concession which one eminent constitutional scholar (Rakove, 1996: p. 157) described as more costly in the long run than the despised three-fifths clause which counted slaves at three-fifths of their total number so artificially boosting southern representation in the lower house of the Congress. Delegates had employed numerous checks and balances to avoid the failure of past republics and made the amendment process unduly cumbersome. Created to meet the concerns of Americans in the late eighteenth-century, it remains the government of the United States in the twenty-first century though the country itself has changed beyond recognition.

Written in the name of the people, the Constitution was submitted to them in specially elected conventions. An early vote of approval was anticipated – the Federalists had the power, the money, and the organization – but as the opposition began to make up ground, the outcome was no longer assured. The Constitution came under attack from many directions. It contained no rights or safeguards; it created a consolidated rather than a federal structure, it would be too powerful, it threatened the states, the size of the lower house was too small, the numbers of congressmen were too few to represent the interests of their constituents; it was too remote. The first major study of ratification was published only in 2010 (Maier, 2010).

Historiography

There is no single narrative of the American Revolution but two approaches, broadly interpreted, tend to dominate its interpretation. Both trace their origins back to the first generation of professional historians who cast the Revolution in two very different contexts: the imperial and the progressive. (For a more detailed account of this earlier historiography see Morgan, 2007) The former approached the Revolution from the perspective of empire, the latter saw the Revolution as a dual struggle about who should rule over America and who should rule in America.

The concept of 'the Atlantic World' developed in the 1980s. Earlier forays into comparative history laid the ground work but when Palmer published his pioneering study of revolution on both sides of the Atlantic, it met with a less than favorable reception (Palmer, 1959, 1964). More successful was Langley's (1998) inter-American study of revolutions in which he compared the patterns of leadership, political history and social character of British North America, Haiti and Latin America. Wim Klooster (2009) examined four Atlantic Revolutions in his comparative study: the American, French, Haitian, and Spanish American, none of which did he think was inevitable and all of which he linked to the vast expenditure on the warfare which preceded them. Critics of the concept point to the fact that the Atlantic is not an enclosed space and its utility as a concept diminishes in the later eighteenth-century. Eliga Gould and Stephen Conway entered a cautionary note, the former pointing to the significance that France still held for the British while Conway stressed the common values shared by the military of both countries. The work of O'Shaughnessy (2000) who reclaimed the Caribbean as an essential theater of war and linked the defeat at Yorktown to Admiral Rodney's dalliance in the West Indies and the plundering of St Eustatius fitted neatly into an Atlantic framework but Armitage's work on the Declaration of Independence did not. Armitage favored a global perspective arguing that the international reception of the Declaration when examined in a global context was more revealing than an Atlantic one since it showed the emergence of a world of states from an earlier world of empires. Jeremy Adelman, however, questioned whether the world of empires can be written off quite so easily since empires could lose large swathes of territory only to reinvent themselves successfully elsewhere in the world. The importance of this wider perspective and longer time frame was evident in Marshall's work which demonstrated how the British succeeded in achieving in India what they failed to accomplish in America – a structure of local government that ensured 'that British territories were effectively defended and that the wealth of the empire was properly husbanded through a system of trade regulation' (Marshall, 2005: p. 12). A global perspective has also proved relevant to historians working on very different types of subjects such as Maya Jasanoff who described her work in *Liberty's exiles* as the 'first global history of the loyalist diaspora.' As 'British power regrouped, expanded and reshaped itself across the world,' she followed the journeys of a small number of loyalist families and individuals (Jasanoff, 2011: pp. 8–11).

Other historians continue to build on the legacy of the progressives and their successors whose work especially in the 1960s and 1970s opened doors to subjects few historians had ever explored. They seek to penetrate below the surface of colonial society as represented by the political and social elite to recover the numerous other actors variously described as 'the people,' the 'ordinary people,' 'the common folk,' and the 'real people,' mechanics, artisans, seamen, plantation slaves, urban slaves, black sailors, the 'middling sort,' women of all classes, Native Americans and loyalists of all sorts. Clearly, they participated in the Revolution – some would say they were the Revolution – but their roles, although becoming clearer, remain relatively obscure especially when compared with the disproportionate amount of time and effort bestowed on the leaders. They made up the crowds who intimidated the stamp collectors, who faced down the customs men and who dumped the East India Company's tea in Boston harbor. They were the enforcers of the Association, the men who filled the ranks of the Continental Army once the early 'rage militaire' was over and the women who ran the households and farms they left behind.

The focus of much of this work was urban. 'It was urban interests that were most threatened, by the Sugar Act, the Stamp Act, the Townshend taxes and the Tea Act' and without crowd action, wrote Countryman 'there would have been no resistance movement' (Countryman, 1985: p. 87). In his study of

urban society in Boston, New York and Philadelphia, Nash argues that the Revolution in these towns was accompanied by a 'profound social upheaval' shaped by preexisting divisions which erupted like a powerful volcano (Nash, 1979: pp. xv–xvi, 340). Ray Raphael (2001), writing history from the bottom up, focuses on army recruits, African Americans, Native Americans, Pacifists and Loyalists and women. Benjamin Carp (2007) asks how different types of urban landscapes shaped the responses of their respective populations to the Revolution. Richard Archer (2010) writes from both the bottom-up and the top-down approaches in his meticulous study of the events that took place in Boston in the years between the Townshend Duties and the Coercive Acts when a standing army swamped the town (Archer, 2010: p. xviii). T.H. Breen agreed that 'the insurgency began not with a familiar cast of American leaders but with the people' but he questioned the emphasis on towns asserting that 'an urban focus is misleading.' Breen reminds his fellow historians that most free white inhabitants lived in small communities comprising a few hundred and in numerous case studies; he reveals their active participation in the Revolution (Breen, 2010: pp. 27, 45–46). Woody Holton shares Breen's focus on the importance of rural society, because in Virginia there were no towns. Small planters made up the bulk of plantation owners in the rural south and Holton and McDonnell ascribe to them a leading role in pushing forward opposition to British policies (Holton, 1999). Native Americans and African slaves were no longer simply victims of the Revolution but active participants in the conflict as demonstrated by Colin G. Calloway (1995); Sylvia R. Frey (1991) and Gary Nash (2006). Nash brings together these fragmented histories, the legacy of the new social history, in *The Unknown American Revolution* (2005) in which he views the legacy of the Revolution for ordinary people as a half finished project, a view also shared by Alfred Young (2006). Terry Bouton, however, reaches a more negative conclusion. If the role of the people is examined over the longer term "to see the Revolution as a democratic victory for the people, one has to cut most of the people out of the story"' (Bouton, 2007: pp. 4–5).

Abstract

When the academic discipline of 'American Studies' was developed in the course of the 1930s, it was explicitly set up as an area of studies where scholars and students of, notably, history and literature could meet and join forces in an integrated, interdisciplinary context in order to redress what was felt to be an increasingly acute challenge: how to bridge the widening gap between the literary and historical approaches to the study of American society. However, the emergence of this new, holistic approach to American society immediately created its own dialectic: between those seeing American society as a whole, and those emphasizing its plurality. Until the 1960s and 1970s, roughly, there was a fair degree of consensus among scholars about what the common denominators were in American society. Ever since the 'culture wars' of the 1980s and early 1990s, however, American studies has come to reflect methodologically the 'cultural crisis' and fragmentation that many have observed in American society itself. Although it may never have become the holistic approach originally envisaged, then, few in American studies would deny that trying to understand and describe American society is in effect an attempt to fathom what sustains that society, what forces operate it and direct its purposes. That is what American studies, from a wide variety of disciplinary angles, continues to do.

When the academic discipline of 'American Studies' was developed in the course of the 1930s, it was explicitly set up as an area of studies where scholars and students of, notably, history and literature could meet and join forces in an integrated, interdisciplinary context in order to redress what was felt to be an increasingly acute challenge: how to bridge the widening gap between the literary and historical approaches to the study of American society. However, the emergence of this new, holistic approach to American society immediately created its own dialectic: between those seeing American society as a whole, and those emphasizing its plurality; between those wanting to highlight American society's unifying myths and symbols as well as its common values and aims, and those drawing attention to its centripetal forces, sometimes identifying these as a dynamics of cultural diversity, sometimes as a tendency toward social segmentation and discontinuity. Even at the beginning of the twenty-first century – as we emerge from the 'culture wars' of the late 1980s and 1990s – it remains difficult to establish any kind of consensus among analysts about the common denominators in American society, about its inner core or even its outer boundaries.

Nevertheless, a number of recurrent themes can be identified that appear to dominate past and present debates in American studies about the nature of American society. Following that society through history, distinguishing the lasting from the transient, the center from the periphery, was one of the original drives behind the emergence of American studies, and this strategy continues to inspire and energize the discipline. Although it may never have become the holistic approach originally envisaged, few in American studies today would deny that trying to understand and describe American society is in effect an attempt to fathom what sustains that society, what forces operate it and direct its purposes. Hence, even though, as Wiebe has argued in *The Segmented Society* (1975), surveying the whole of a society always tends to emphasize social patterns rather than social processes and to subordinate 'a history of themes inside American society to a history of the society incorporating them,' one may still look meaningfully at those themes, and at the history of their emergence and development. That is what American studies, from a wide variety of disciplinary angles, continues to do.

Terms and Periods

Apart from qualifying the unanimity among scholars in American studies regarding the object and methodology of their inquiry, a further note of caution should be sounded concerning terminology. Within the discipline of American studies – itself an umbrella term – the term 'society' is usually taken to refer to the aggregate of the politics, history, economics, education, geography, religion, environment, and culture of the United States, as well as to the relations and tensions between these elements. However, many Americanists, especially those approaching their object from the realms of literary analysis, the history of ideas, and 'cultural studies,' would refer to the same grouping of aspects of American society and the interplay between them as American 'culture.' As Potter remarked in *History and American Society* (1973), this terminological confusion is symptomatic of 'a serious general problem in the study of societies,' viz. the lack of fixed points of similarity in different societies, and between different aspects of societies, with which to measure continuity and separateness. For the sake of clarity (and following Wiebe), 'culture' will here be defined in its more narrow sense as 'those values and habits conditioning everyday choices in such areas as family governance, work, religious belief, friendship, and casual interchange,' while 'society' will be seen as combining 'these patterns with broader and more systematic realms of behavior, such as the organization of a community's life, the structure of a profession or business or religious denomination, and the formula for apportioning economic rewards.'

Traditionally, the evolution of American society during the first two hundred years since the Revolution has been divided into three phases, each associated with a distinctive social system: from the Revolution to the 1790s; from 1830 to 1890; and from 1920 to the 1970s. The intervening years – from the 1800s to the 1830s, and from the 1890s to the 1920s – are seen as crucial periods of transition from one social system to the next: from 'eighteenth-' to 'nineteenth-,' to 'twentieth-century society.' Whether the last three decades of the twentieth century constitute a fourth phase in American society (cf. for instance Lipset, 1979 [1980]), or a continuation of the transitional period of the 1960s and 70s, or, indeed, the 'disuniting of America' altogether as signaled by others (cf. Schlesinger, 1991 [1993]), is still a moot point. In the following, aspects of American society that have dominated debates and explorations in American studies will be discussed in terms of their emergence and evolutionary history.

Seventeenth- and Eighteenth-century Society

American society, one often reads in accounts of the settlement and early colonization of North America, began with a dream – a vision of a morally pure, socially just New Eden, itself the reflection of a long tradition of European utopianism. European observers and settlers alike represented seventeenth- and eighteenth-century American society in terms of a transatlantic opposition that is still relevant today: an opposition between Old World corruption and New World innocence, between darkness and light, between stasis and progress. For even if the early American settlers were a motley crowd internally divided by differences of ethnicity, language, ideology, religion, politics, and commercial interest, there was always a remarkable consensus among them about what America was, or was supposed to be – a society that, defining itself against the backdrop of European wars, exploitation, inequality, and persecution, was somehow unique, whole, progressive, and civilized.

More remarkable than that, perhaps, was that, despite their differences, the various stakeholders in the new nation were all prepared, if for very disparate reasons, to rally round a symbol of American society first provided by one radical group of early settlers, the New England Puritans. As early as 1622, Puritan leader John Winthrop labeled England as 'this sinfull land,' plagued by poverty, inequitable taxation, a bureaucratic legal system, and religious intolerance; as the first elected governor of the Massachusetts Bay Company, Winthrop set off for New England in 1630, envisioning a 'city upon a Hill' as the utopian foundation for the new society that he and his fellow Puritans would be building. The New England Puritans may have had fairly specific religious reasons for regarding their community as a model for other colonists and as the first step toward establishing a kingdom of God in the New World that would lead the world into a new millennium, but the image of America as 'a beacon upon a hill' sufficiently reflected the ambitions of other, non-Puritan settlers for it to be adopted widely as one of the most resonant and sustaining symbols of American society, both in qualitative, intrinsic terms, and in its relation to the rest of the world. Thus, long after the waning of the Puritan theocracy, the founding fathers of the 1630s continued to be ritually invoked as heroes in the cause of liberty – not just in New England, but throughout other Eastern States and the South, and as much during the Great Revival as during the French and Indian War and the Revolution. The epic of the Puritan exodus became the common property of all Anglo-American settlers, and the rhetoric and ideology of the Puritan religious errand into that 'unredeemed, unchristianized, lawless region' (as Hawthorne put it) became the rhetoric and ideology of America's cultural errand into the 'wilderness.'

As a symbol reflecting the internal dynamics of the group, the idea of America as a bridgehead of civilization beleaguered by a 'vast and desolate wilderness' (Rowlandson, 1682 [1994]) to an important degree determined the social mechanics of what has been termed 'the ritual of consensus' (Bercovitch, 1993). Faced as they were by the challenges of survival and success, consensus filled the need felt by Puritan and non-Puritan settlers alike for a certain social order. In particular, such a ritual of consensus had to regulate the rights and responsibilities of the individual versus the group. According to Bercovitch, there were three basic tenets of Puritan consensus, which in the course of the seventeenth century transformed from a tribal ritual into a national ritual of cultural and social origins. The first tenet was migration, as a function of divine mission or prophecy – which contributed significantly toward rationalizing the expansionist and acquisitive aspects of settlement (the Puritans being as much interested in material gain as in salvation). The second tenet of consensus was related to discipline: seeing that an individual's success made visible the meaning of the errand of the group, the challenge was how to endorse individualism without promoting anarchy. The third tenet of consensus was concerned with progress: constantly affirming that it was en route from a sacred past to a sacred future, the Puritan community established institutions that were geared more toward sustaining progress and growth than toward maintaining stability. Crucially, the Puritan ritual of consensus was constantly enacted – both in the sense of established in law and in the sense of publicly performed – in a series of interlocking covenants to which individuals were invited to subscribe their names if they wanted to be regarded as members of the community. The first and most famous of such civil covenants, the 'Mayflower Compact' (which was signed in 1620 by the Pilgrim Fathers on board the ship that took them to what was to become Plymouth Plantation), reflects how these covenants were aimed at establishing a 'Civil Body Politic' by preserving individual freedom while demanding submission to 'the general good.' It is this Puritan rhetoric of voluntary compacts and consensus, of community grounded in individuals committing themselves freely to their 'common providence,' that gave American society its unique slant on the universal process of introducing systematic relationships among individuals, groups, and institutions; and it is the same rhetoric that, being both universal yet culturally specific, facilitated the transition from the Puritan to the Yankee, and from errand to manifest destiny and the American Dream. It is the legacy of the Puritan errand that lies at the basis of America's social awareness vis-à-vis the world at large: America as the 'redeemer nation,' which, according to Tuveson (1968), can be reduced to the following key elements: 'chosen race; chosen nation; millennial-utopian destiny; fighting God's war between good (progress) and evil (regression), in which

the United States is to play a starring role as world redeemer.' Thus, when Woodrow Wilson said that 'America had the infinite privilege of fulfilling her destiny and saving the world,' he was not saying anything startlingly new.

In the course of the second half of the eighteenth century, the spiritual and the more secular beginnings of American society (symbolized by Plymouth Plantation and Jamestown, respectively, by the 'beacon on the hill' and the Horn of Plenty) had become sufficiently blended for Crèvecoeur to be able to pose the notorious question in his *Letters from an American Farmer* (1782 [1981]), 'What, then, is the American, this new man?' and to assume – or suggest – that this was actually more than a rhetorical question: that there really was such a social subject as 'an American.' What in hindsight is perhaps even more perplexing than Crèvecoeur's question as such, is his answer to that question: Crèvecoeur's 'American' and the society he is said to have created are still by and large what we would recognize as American national identity and society today. An immigrant newly arrived in America, Crèvecoeur informs us, would find himself 'on a new continent; a *modern society* offers itself to his contemplation, different from what he had hitherto seen.' He would see a society that is egalitarian and classless, in which individuals are 'animated with the spirit of an industry which is unfettered and unrestrained, because each person works for himself.' The world's poor, oppressed and persecuted will find safety and plenty of opportunity in 'this great American asylum.' To underline the radical modernity and uniqueness of this new society, Crèvecoeur assures us that in America 'individuals of all nations are melted into a new race of men, whose labours and posterity will one day cause great changes in the world.' The millennial dreams of the New England Puritans have in Crèvecoeur's *Letters* become America's millennial dreams – now all Americans are 'pilgrims': 'Americans are the Western pilgrims who are carrying along with them that great mass of arts, sciences, vigour and industry which began long since in the East; they will finish the great cycle.'

Nineteenth-century Society

The individual's 'self-interest' and his concomitant voluntary submission to his nation's mission form the nucleus of Crèvecoeur's America – and they still do. The American Revolution, which ended the colonial stage in the evolution of American society, did not therefore constitute that sharp, radical break it has traditionally been made out to be. Since the end of the French and Indian War, self-interest had been synonymous with (Protestant) patriotism, and it was through their appeal to this patriotic self-interest that the Revolutionary leaders managed to steer the colonies victoriously through the conflict with Britain and toward nationhood. Thus, while Crèvecoeur's distressed frontiersman announces in his final letter (burdened by his creator's nostalgia for utopian pastoralism) that in 'these calamitous times' he feels forced to flee his farm and to resettle his family 'under the wigwam' in the western wilderness, the Whig leaders succeeded in bringing the violence and disruption of the Revolution under control by turning it into a redemptive, controlling ritual of national identity. The push for independence, which elsewhere (most notoriously in subsequent years in France) often triggered a complete collapse of the social fabric as the forces of change spun out of control, in America engendered a spirit of intense nationalism and enforced the model of consensus. What the Puritan Fathers had begun – overcoming discord in society by turning anxiety into a vehicle of social control – was now finished by the Founding Fathers.

With the 'family quarrel' – so unfortunate but necessary – finally over, America was ready to enter the final phase of its evolution toward full nationhood; the Revolution having given America independence from the Old World, it was now time to complete the errand into the wilderness by going west, not to hide under a wigwam, but to conquer the continent. Space and diversity, as Madison had argued in *Federalist Number Ten*, would be the best guarantors of liberty, because a dispersed and heterogeneous nation would be able to contain more factiousness than a compact and more homogenous one. And the dangers of faction were increasing all the time in the wake of the Revolution, as the system of graded and interlinking social relationships of eighteenth-century society – marked by paternalism, the moral economy, and virtuous republicanism (or 'civic virtue') – began to give way to an increasing emphasis on personal mobility – social mobility as well as geographical.

Uncurbed social ambition and a vigorous spirit of enterprise led to a rapid crumbling of deferential restraints, and the meaning of American wholeness came under significant pressure during these years of transition. The old household economy of colonial America had gone into a complete nosedive in the 1790s; fuelled by the stirrings of industrialism, the opening up of the west, the Louisiana Purchase of 1803, and the Napoleonic Wars in Europe (which virtually eliminated mercantile competition), liberal capitalism triggered a socio-economic revolution that transformed the United States in the course of two decades into a market economy and market society. The end of the War of 1812 gave a further boost to America's economic revolution, with a rapidly growing immigrant population, and the building of the canals and the early railways permitting the republic to enter an era of unprecedented expansion, especially toward the vast western regions.

American geopolitics in the early decades of the nineteenth-century to a large extent shaped the growing awareness of nationhood and state. This resurgence of nationalism peaked with the so-called 'Monroe Doctrine,' which basically meant that the United States declared they would not accept any future colonization by European powers of 'the American continents.' But in social terms a price had to be paid for America achieving hegemony in the Western Hemisphere, and a controversy erupted over the question of not whether, but how the nation should be allowed to expand. With the election of Jackson as President of the United States in 1829 a powerful democratic movement swept the country, paving the way for mass politics and what was called at the time 'the age of the common man.' The fight against social and economical inequality and privilege dominated the national political agenda. And although there is still considerable disagreement among historians as to how much of this drive toward democratic reform and anti-elitism can actually be attributed to Jackson and his followers, the reaction against laissez-faire capitalism from among the working classes and other exploited groups in the new industrial society was considerable.

Liberty and equality became the cornerstones of the new American society – even though the veneer of egalitarianism did not affect a host of distinctions underneath (notably those of race and gender).

A tourist like the French aristocrat Alexis de Tocqueville, who came to America in the 1830s to discover why the efforts at establishing democracy in France, starting with the French Revolution, had failed while the American Revolution had produced a stable democratic republic, may not have seen far beyond the surface respectability but he did make some seminal comments on American egalitarianism. According to Tocqueville, America was 'the first new nation' in the world. In fact, it was Tocqueville who first referred to the United States as 'exceptional,' that is, as a nation qualitatively different from other nations. In his extraordinarily influential book *Democracy in America* (1835–39 [1945]), Tocqueville identified five elements in the American Creed as it had emerged from the revolutionary ideology – liberty, egalitarianism, individualism, populism, and laissez-faire – but, as Tocqueville pointed out, egalitarianism in American involves an equality of opportunity and respect, not of result or condition. Therefore there is no emphasis on social hierarchy in America – no monarchies or aristocracies (which distinguishes the United States from post-feudal nations as such) – although there is social segmentation. It is this, Tocqueville noticed, and many others since him, that was central to American exceptionalism: 'What held Americans together was their ability to live apart …. From this elementary principle emerged a pattern of beliefs and behavior that was recognizably American' (Wiebe, 1975).

The idea of space as a sine qua non of liberty and equality was popularized at the end of the nineteenth century by the historian Frederick Jackson Turner. At a point in America's history when, he claimed, the vast, unsettled lands were gone, Turner identified the westward expansion of the United States as the crucial formative force behind American individualism, nationalism, and democracy. Because he had to constantly reinvent himself and reconfirm his essential Americanness as he pushed further west, the frontiersman, Turner argued, had defined American civilization. With the waning of the western wilderness, a crucial period in American history had closed. In fact, Turner's concerns turned out to be rather premature as in the decades following his bemoaning of the 'passing of the frontier' the US government gave away more land from the public domain than it had done before – but the 'frontier myth' kept a romantic image of the West alive for long after.

Twentieth-century Society

If, as historian Richard Hofstadter, 1948 has observed, it has been America's 'fate as a nation not to have ideologies, but to be one,' then that ideology was very much in place at the beginning of the twentieth century. But although the ideology did not change materially from that of the late nineteenth century, the face of society did. One of the most conspicuous developments was the emergence of a new social elite – the occupational elite. The end of the nineteenth century saw an explosion of the number of Americans in administrative and professional jobs. Industry and the new technologies needed managers, technicians, and accountants; cities needed professionals in the medical, commercial, legal, and educational services. By the turn of the century, these new professionals had come to constitute a distinct social group – the new middle class.

Although the new professional class enabled individuals to climb the social ladder more rapidly than in the nineteenth century, the new class was by no means any more homogeneous – the nineteenth-century segmentation of society on the basis of region, ethnic background, and access to capital was replaced by a segmentation according to professional occupation – each segment (clerks, technicians, lawyers, teachers, engineers) having its distinct identity and social awareness, and the vitality of each depending on the vitality of the whole.

While diversity remained the common denominator in society, the need for cohesion in the national society never disappeared – the ideology of consensus still being as strong as in the days of the Puritans. If in the nineteenth century the outrage of national conscience had directed itself against sloth, drunkenness, and profligacy, in the twentieth century the social hegemony aimed its arrows at the leveling left, communists, and other 'un-American' elements (descendants of Crèvecoeur's 'off-casts') that threatened to undermine the 'volutary order' (Berthoff, 1971).

But the most powerful cement of the new social system was consumption. Starting hesitantly in the latter decades of the nineteenth century, accelerating in the 1920s, and exploding in the 1950s, consumption became the foundation for the modern America. By the 1960s, consumption was no longer a privilege but a right – to some extent even a civil duty. Consumption became everybody's stake in society – the ultimate equalizer. In the course of the twentieth century, Americans began to regard the meaning of work as the power to spend, and increasingly began to discover their identity and social position in their power to consume. Mass consumption became an inalienable right. Women derived their freedom from being primary consumers; consumption was an effective weapon against communism; and the urban African-Americans who looted shops during race riots thereby underlined the fact that they were still being denied their basic civic right: the right to consume.

Consumption has been regarded as the ideological twentieth-century answer to the challenges of differences of class and civil rights. The nineteenth century had failed to manage the problems of class; the economic elite of the twentieth century quite early on accepted class as a social fact. By quickly and consistently demolishing labor organizations and any manifestations of socialism wherever they appeared, and simultaneously offering occupational segmentation as a new model of social mobility, the threat of class conflict was contained. The importance of regular employment was paramount to egalitarianism for the credit it generated: for it was the credit that made the professional or worker a consumer, and the consumer a citizen. In a similar way, twentieth-century society put paid to the issue of race conflict: the economic elite offered members of minorities as well all other Americans a passport to consumerism and a place somewhere in the great interdependency of the system of segmented wholeness. Race, like class, simply was no longer relevant from a socioeconomic point of view. Racial or other minorities can either aspire to

assimilate to the segmented system, even to belong to the social elite, or they can decide to rely on such benefits as are provided within the context of social security.

The much-touted revolutionary drive of the 1960s' 'counterculture' did not materially change the system of segmented wholeness. For a while it looked as if there might be more emphasis on the common denominators in American society, as if there were an America beyond the segmented system (classless, gender-neutral, race-neutral). Indeed, changes in the overarching social fabric have occasionally been affected by pressure from within one or more of the segments (such as racial desegregation, and a more equitable job market). But, by and large, America has remained essentially a nation of segments. However, if America still subscribes to this concept of nationality, it does so voluntarily. In contrast to the rest of the world, as Gover (1948) has observed, Americans believe that nationality is 'an act of will, rather than of chance of destiny.'

That is what Europeans have never understood about America, according to Baudrillard (1986 [1988]). He argues that the great lesson of the success of America's social formation is that 'freedom and equality, like ease and grace, only exist where they are present from the outset. This is the surprise democracy ha[s] in store for us: equality is at the beginning, not the end. That is the difference between egalitarianism and democracy: democracy presupposes equality at the outset, egalitarianism presupposes it at the end. "Democracy demands that all of its citizens *begin* even. Egalitarianism insists that they all *finish* even."' Whereas Europe has remained stuck in the old rut of social difference and is constantly dragged back into the history of its bourgeois culture, America, by contrast, has achieved a state of radical modernity, which in temporal terms can be described as a perpetual present. Having internalized democracy and technological progress, America ducks the question of originality, descent, and mythical authenticity. Everything is exactly what it appears to be in America: the real and the imaginary have been collapsed into the 'hyperreal,' – a constant state of simulation, of signs having escaped their referentials in the real. The concept of history as 'the transcending of a social and political rationality, as a dialectical, conflictual vision of societies,' is alien to Americans, Baudrillard observes: the United States is, in fact, a utopia achieved – a society which has behaved from the beginning as though it were already achieved.

American Society and American Studies

Baudrillard's incisive observations about American society are not unchallenged within the social sciences, but despite the provocative rhetoric, it cannot be denied that his concepts of the 'hyperreal' and the 'utopia achieved' are valuable tools in trying to account for some of the more paradoxical complexities of American society – its fragmented wholeness; its social stability in the face of an unequal distribution of wealth; its belief in 'a pleasing uniformity of descent' (Crèvecoeur 1782 [1981]) and a 'general happy Mediocrity' (Franklin, 1791–1798 [1986]) when the racial divide appears to be as wide as ever. Baudrillard's agenda – to bring the paradoxical nature of American society into a universal model while retaining the apparent incompatibility of its constituent parts – is certainly unique in the evolution of American studies. From its inception in the 1920s, the discipline of American studies has almost inescapably been concerned with the search for the common denominator in American culture and society: the very success of its mission – to establish and institutionalize a scholarly discipline whose object of study was the society of the United States – depended on the new discipline being able to achieve some sort of consensus about the nature of that object of study.

This mission first took off seriously with the publication of Vernon Parrington's *Main Currents in American Thought* (1927 [1958]), and was carried further with enthusiasm by the 'consensus historians' of the 1950s (including Richard Hofstadter, Louis Hartz, Arthur Schlesinger, Jr., Daniel Boorstin) and, most importantly (in terms of its impact on the field), by the 'myth and symbol' school of the 1950s (which included intellectual historians and literary critics such as Lionel Trilling, Henry Nash Smith, R. W. B. Lewis, and Leo Marx). The 'myth and symbol' scholars had indirectly been influenced by a host of literary critics in the 1930s and 1940s who were known collectively as the 'New Critics.' Approaching the literary text as an autonomous whole, the New Critics (which included such people as John Crowe Ranson, Kenneth Burke, Yvor Winters, and R. P. Blackmur) emphasized the transcendental qualities of the text: its moral content; its symbolic meaning as a reflection of national culture and identity; and its place and contribution to a national literary 'tradition.' F. O. Matthiessen's extraordinarily influential *American Renaissance: Art and Expression in the Age of Emerson and Whitman* (1941) established a 'great tradition' of nineteenth-century American authors that represented the 'quintessential' characteristics, concerns, and values of 'mainstream' American society. Inspired by the humanistic ideal of high culture, Matthiessen's canon of nineteenth-century American literature not only introduced a firm hierarchy of 'high' over 'low' artistic expression but also provided the raw cultural materials for the authors of the myth and symbol school. In this way Smith's thesis of the wilderness as the basic ingredient of American civilization, Lewis's insistence on tragic innocence in the myth of the 'American Adam,' and Marx's symbol of the 'machine in the garden' to account for the 'American' dichotomy of pastoralism and technological progress could become the unifying myths and symbols that dominated the study of American society during the 1950s and 1960s.

When, in the course of the 1960s, mainstream American society and culture increasingly came under attack from historically marginalized groups as part of the struggle for emancipation and recognition (women, African-Americans, Native Americans, Hispanics, gays, and other minorities), the theory and methods of American studies were also subjected to critical analysis and reappraisal. If pluralism replaced universalism as the new norm in society, so it did in American studies. Thus the new social history that emerged in the late 1960s and early 1970s began to demolish American exceptionalism, imperialism, and the consensus society, while it tried to recover or create the history of America's 'forgotten' minorities, as well as America's popular culture, and its labor and regional history. Drawing from the techniques and methods of sociology, anthropology, and other human sciences, gender, class, and race became the new 'holy trinity' of American studies.

Increasingly, also new criticism and the myth and symbol school came under attack for being ahistorical and for their philosophical idealism. With the emergence of the 'New Historicism' (ushered in by Stephen Greenblatt and the journal *Representations*) interdisciplinarity and historical contextualization were put firmly on the methodological agenda of American studies. This paradigm shift is illustrated by a seminal collection of essays edited by Sacvan Bercovitch and Myra Jehlen, *Ideology and Classic American Literature* (1988), which contains reassessments of their work by important pioneers of American Studies theory and method including Henry Nash Smith, Leo Marx, and Alan Trachtenberg, as well as essays by a younger generation of scholars, including Houston Baker, Carolyn Porter, Donald Pease, Michael Gilmore, Jane Tompkins, Jonathan Arac and Myra Jehlen – work that exemplified the scholarly output of the 1980s, blending feminist, neo-Marxist, and poststructuralist theories and methods.

However, whereas among the newly emancipated groups this pluralist approach to American society was experienced as liberating (both intellectually and politically), a growing number of scholars began to interpret the new trend toward plurality as undesirable. Christopher Lasch was one of the first to sound the alarm bell. In *The Culture of Narcissism* (1979 [1991]) he argued that the 'devaluation of the past' was symptomatic of a deep 'cultural crisis,' and he accused the 'demoralization of the humanities' of having reduced American 'individualism' to 'a narcissistic preoccupation with the self.' With the publication of Allan Bloom's *The Closing of the American Mind* (1987 [1988]) the 'battle of the books' erupted into an all-out 'culture war.' According to Bloom, the social/political crisis of twentieth-century America was really an intellectual crisis. Despite the use of such edifying labels as 'individual responsibility, experience, growth, development, self-expression, liberation and concern,' Bloom argued, the 1960s had 'bankrupted' American universities and destroyed 'the grand American liberal traditions of education.' The battle over the canon of American literature was now openly a battle about the canon of American culture and society, about nationality and multiculturalism, about consensus and political correctness. The 1990s saw a whole spate of books calling for a truce and reconciliation, offering a wide array of solutions to the increasingly vicious national debate and the resulting ideological stalemate. In *Beyond the Culture Wars* (1992 [1993]) Gerald Graff showed how 'teaching the conflicts can revitalize American education,' while Henry Louis Gates, Jr. advocated in *Loose Canons: Notes on the Culture Wars* (1992) a new civic culture that would transcend the sharp divisions of nationalism, racism, and sexism. Schlesinger rather desperately proposed in *The Disuniting of America* (1991 [1993]) that Americans should attempt 'to vindicate cherished cultures and traditions without breaking the bonds of cohesion – common ideals, common political institutions, common language, common culture, common fate – that hold the republic together'; this appeal was picked up by David Hollinger, who argued in his *Postethnic America* (1995) that Americans should form 'voluntary' rather than 'prescribed affiliations' to bridge the ethnic and multicultural gaps in society.

There are no clear signs that the latest models of reconciliation have effected any kind of movement on the battleground of nationality and multiculturalism – which perhaps is not surprising since the majority of them propose as the solution to the threat of the radical implosion of the consensus model of American society a return to the very neo-humanist, essentialist ideals that are so vehemently being contested in the multiculturalism/pluralism debate. In the meantime, the discipline of American studies is as divided as the various participants in this debate. However, although there has been some degree of disciplinary backlash (with some academic programs having been reduced or cut from university calendars), most working in the field would concede that the questions about the future of American culture and society have never been as open as they are at the beginning of the twenty-first century, and that this in itself more than legitimizes the continuing study of American society within the interdisciplinary framework of American studies.

Abstract

The seven countries in the Central American subcontinent – Belize, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama – have, to a certain degree, followed their own social and historical trajectories in the early years of the twenty-first century, but each nation has been indelibly transformed by globalization. This article explores recent changes in the political, economic, social, and cultural life of the region, with special emphasis on new forms of identity and citizenship that have emerged since the late 1980s.

The seven countries in the Central American subcontinent – Belize, Costa Rica, El Salvador, Guatemala, Honduras, Nicaragua, and Panama – have, to a certain degree, followed their own social and historical trajectories in the early years of the twenty-first century, but one can identify common patterns in their recent histories. Each Central American nation has been indelibly transformed by globalization, the integration of the world's nation-states into a single economic and cultural system that is strongly oriented toward the interests of transnational capital. While Central America has been tightly woven into the world economy since the colonial period, the past two decades have been marked by rapid, widespread changes in economics and politics – produced by globalization – that have reverberated through all aspects of society, profoundly reshaping everyday life throughout the region. As a result, in the past 20 years, social scientists have tended to study Central American sociocultural life within a global frame, describing how particular communities, regions, or states are transformed by macrolevel changes in political economy.

Cold War Legacies

In order to understand the impact of globalization on Central American society, one must first recognize that the present era emerged in the aftermath of revolutionary violence. Caught along the fault lines of the US-Soviet conflict, Central America in the 1980s was defined by war. The conflict began with the Cuban Revolution of 1959, which inspired revolutionary movements in El Salvador, Guatemala, and Nicaragua. In each country, a small group of guerillas sought to overthrow corrupt and oligarchic political regimes by force. While the revolutionary fronts were inspired by different ideologies, including Maoism, Soviet communism, and other variants of postcolonial revolutionary thought, they all sought to build support among the rural poor to overthrow the state to bring about a more equitable social order. In response to the threat of leftist revolution in its own backyard, the United States government supported military action against the revolutionaries, providing weapons, training, and financial support to dictatorial regimes in El Salvador and Guatemala. In Nicaragua, the Sandinista revolutionaries successfully overthrew the Somoza government in 1979 and remained in power until 1990. The United States supported and trained the Contra counterrevolutionaries, who carried out a guerilla war against the Sandinistas, who were supported by the Soviet bloc and Cuba.

Belize, Costa Rica, and Honduras did not directly experience large-scale war in the 1980s, but they were affected by it. Honduras, and, to a lesser extent, Costa Rica, were bases of operations for the Nicaraguan counterrevolutionaries. Foreign military and economic aid poured into the region as a strategy to ward off the threat of revolution, and refugees and displaced migrants flowed into all countries that bordered the war-torn regions. The Central American peace process began to take shape in 1987, led by Costa Rican president Oscar Arias, who was awarded that year's Nobel Peace Prize. Beginning with regional meetings held in Esquipulas, Guatemala, the governments of Guatemala, Nicaragua, and El Salvador created a framework to end the wars and establish democracy. Nicaragua held elections in 1990, leading to the electoral defeat of the Sandinistas. The war in El Salvador ended with a peace agreement in 1992, and Guatemala's war ended with the signing of Peace Accords in 1996.

Since the end of the wars, each country has been forced to come to terms with the legacy of mass violence. In El Salvador, more than 75 000 people lost their lives during the war, and a million people were displaced. In Guatemala, tens of thousands of people – mostly indigenous Maya – were killed in a war that was called genocide by the United Nations. Anthropologists have focused on the complex negotiations of blame and healing that mark postconflict societies. In Guatemala, Diane Nelson (2009) and Victoria Sanford (2004) describe the lingering sense of horror that has emerged as the country comes to terms with mass violence, and where, despite the presence of truth commissions, some of the worst abusers of human rights continue to live with impunity. In El Salvador, which is sometimes described as a model of postconflict stability and democracy, Ellen Moodie (2010) has shown how postwar society remains beset by violence and insecurity that seems difficult to understand and explain than what occurred during the Civil War. While peace has officially come to El Salvador and Guatemala, both countries are still working to heal a traumatized body politic.

Within anthropology, the struggle to come to terms with the violence of the 1980s led to the so-called Rigoberta Menchú Controversy (Arias, 2001). The controversy began in the late 1990s when anthropologist David Stoll published a book

(Stoll, 1999) that used ethnographic and historical research to disprove some of the claims made in *I Rigoberta Menchú*, a world-famous biography of Mayan activist Rigoberta Menchú Tum, written by Elisabeth Burgós-Debray in 1982. *I Rigoberta Menchú* played an invaluable role in raising the world's awareness about the atrocities committed by the Guatemalan military against the Maya. Menchú became a worldwide symbol of indigenous resistance, traveled around the world to speak, and was awarded the Nobel Peace Prize in 1992. Stoll's research called into question some of the details of Menchú's account of her life. At a broader level, his book argued that urban intellectuals in Europe and the Americas romanticized Latin American revolutionary movements, turning a blind eye to some atrocities that the revolutionaries committed against the rural poor that they claimed to help. Although Stoll did not intend to criticize the larger truth of Menchú's story, he argued that scholars had glossed over important complexities of the revolution due to their sympathies for the revolutionary cause. The book made headlines around the world, and was used by critics to discredit Menchú. The entire affair instigated an emotionally charged debate about the politics of anthropological knowledge: Is scholarly objectivity desirable or possible in a situation of violent conflict? And should the value of scholarship be measured by its political effects, or by a disinterested standard of truth? In hindsight, the Menchú controversy played out as a scholarly analog to the truth commissions, in that it generated a difficult – and unresolved – conversation about the role and responsibility of scholars in a complex and violent world.

From Revolution to Remittances

As the revolutionary period subsided, scholars who had focused almost exclusively on the causes and consequences of war in Central America in the 1980s began to focus on new transformative changes in the region, none more significant than the rapid increase in migration to the United States from El Salvador, Guatemala, Honduras, and Nicaragua. It is not a coincidence that the countries that were most impacted by war became the major sources of migration to the United States. Between 1980 and 2010, the number of Central Americans living in the United States increased by at least a factor of 20. Prior to the 1970s, Costa Ricans and Panamanians composed the largest percentages of total Central American migration to the United States, which was still relatively small, approximately 100 000 in 1970. In the late 1970s, displaced people and refugees fleeing El Salvador, Guatemala, and Nicaragua began to enter the United States in large numbers, and in the 1980s, the number of Central Americans entering the United States tripled that of the previous decade. As of 2010, approximately 1.2 million people born in El Salvador were living in the United States, along with 800 000 from Guatemala, 500 000 from Honduras, and 250 000 from Nicaragua.

The so-called Central American diaspora has transformed economy, culture, and society throughout the region. By 2011, migrant remittances accounted for almost 20% of GDP in Honduras, 15% in El Salvador and Nicaragua, and 10% in Guatemala. The social and cultural changes brought about by migration were just as significant as its economic impact. Rural communities that had been historically dependent on agriculture came to rely on remittance payments from young men and women in the United States. Formerly isolated towns and villages became socially and culturally connected to cities and towns in the United States, leading to rising consumerism, changes in family dynamics, and new concepts of status and value. Migration has also transformed the relationship between rural and urban areas around the region, turning impoverished rural communities into sites of economic growth. In El Salvador, Sarah Mahler (1995) has described the chain of migration that developed between suburban Long Island and the rural department of La Unión in the 1980s. David Pedersen (2013) describes the rapid transformation of town of Intipucá, also in La Unión, as a result of large-scale migration to Washington, DC that began in the 1980s. Patricia Foxen (2007) describes a similar process that took shape in Guatemala, where Mayans from the community of Xinxuc began to emigrate to Providence, Rhode Island, in the 1980s, creating a transnational circuit that has endured for decades since. In Honduras, which has become the most remittance-dependent country in the region, the boom in migration to the United States began later than it did in El Salvador, Guatemala, and Nicaragua, caused mainly by economic factors (such as a sharp decline in world coffee prices in the early 2000s) and the after effects of Hurricane Mitch, which devastated the country in 1998 (Reichman, 2011). Despite these differences, migration has transformed Honduran society in ways that are quite similar to what has occurred in El Salvador and Guatemala.

Central American politicians have responded to the newfound influence of migrants. Across the region (particularly in El Salvador and Honduras) hometown associations, groups of organized migrants abroad, have supplied funds for municipal development in their native countries. A host of programs has been developed to lessen the expense of remittance payments for senders and recipients, in order to keep more capital 'in the pockets' of remittance-dependent families. NGOs, governments, and international aid organizations have created pilot programs to supplement the work of hometown associations with public funds in order to support rural development. Noting the direct impact that small amounts of remittances can have on family well-being, El Salvador, Guatemala, Honduras, and Costa Rica have all created conditional cash transfer programs to give direct economic assistance to poor families.

While migration and remittances have provided a much-needed source of income to rural families, they have also created a new form of dependency on the United States. Central American economies have long been economically dependent on the United States, the region's most important trading partner and source of foreign investment, but migration-dependency has added a new wrinkle to this enduring pattern. Changes in US immigration law now directly affect families throughout Central America, and the fortunes of rural communities are tied to the vicissitudes of immigration politics in the United States. In 1986, for example, the United States passed the Immigration Reform and Control Act (IRCA) which legalized more than two million unauthorized immigrants. This law provided a way for the relatives of hundreds of

thousands of Central American migrants to enter the United States legally under family reunification visas. The 1986 law also greatly intensified the enforcement of immigration law, including border security, and this crackdown on unauthorized immigration has continued for the past 25 years, creating a sophisticated, militarized border security complex called the 'deportation regime' (De Genova and Peutz, 2010).

The deportation regime, which reached its peak in the years after the attacks of 11 September 2001, had far-reaching impact on Central America. Elana Zilberg (2011) describes how the deportation of El Salvadoran gang members from Los Angeles led directly to the growth of organized crime in El Salvador. Gangs such as the MS-13 have gained infamy around the world, and their existence is directly tied to the illicit trade in narcotics across the Americas, as well as the smuggling of unauthorized immigrants through Central America and Mexico. At a broader level, the demand for immigrant smugglers to help desperate people across a militarized border has created a complex web of corruption, organized crime, and exploitation that reaches across the Americas.

Rates of violent crime have risen dramatically in El Salvador, Guatemala, and Honduras in the 2000s. Gangs (called maras) have become a specter of disorder and criminality across Central America, and fear of gangs has helped to drive the popularity of rightist governments that claim to restore 'law and order' to a body politic threatened by 'delincuencia.' In Honduras and El Salvador, antigang measures known as mano dura (iron fist) have led to brutal crackdowns against suspected gang members, measures that involve suspension of due process and basic civil rights. While the threat of gang violence is real, it has revived some of the authoritarian measures that were used against suspected political enemies under military dictatorships. The hardline tactics have also led to severely overcrowded prisons, which have been home to several violent prisoner riots, most notably in Honduras, where a suspicious prison fire in the provincial town of Comayagua killed 360 people in 2012.

Neoliberalism and Its Opponents

If the 1980s were the decade of war in Central America, the 1990s were the decade of neoliberal globalization. From about 1950 to the late 1980s, governments sought to gain control over national economies by promoting domestic industry and creating policies that would keep profits from leaving Central America. These policies – sometimes called protectionism or economic nationalism – were viewed as an alternative to the neocolonial exploitation that had shaped the region in the modern era. For much of the twentieth century, in places like Honduras, Guatemala, and Costa Rica, foreign capital was often equated with export industries like banana cultivation, mining, and coffee production, which created severe inequality, corruption, and environmental damage. Neoliberalism marked a sharp turn away from economic nationalism, in that it welcomed foreign corporations as agents of economic growth, rather than exploitation. Neoliberal doctrine promoted privatization and openness to foreign trade. It directed governmental expenditures toward areas that would improve a country's competitiveness in the global economy, prioritizing economic growth over social stability. Under the guidance of the World Bank and the International Monetary Fund, neoliberal policy became the most popular recipe for economic growth in Central America in the 1990s.

The most apt symbols of neoliberalism in Central America are the free trade manufacturing zones that have popped up in every country in the region, designed to create economic growth by attracting foreign direct investment. In some cases, such as Costa Rica and Panama, this strategy has yielded notable benefits. In the former, the high-tech manufacturer Intel has become the largest company in the country. In the latter, the free trade zone along the Panama Canal, under Panamanian control since 1999, is one of the world's most important export manufacturing hubs. In Honduras, Guatemala, Nicaragua, and El Salvador, free trade zones are referred to as *maquilas* or *maquiladoras*. They are specially zoned industrial districts that house foreign-owned manufacturing plants, which often specialize in the manufacture of textiles, housewares, and footwear for export, mainly to the United States. These facilities, disparaged as 'sweatshops' in the United States and Europe, attract foreign capital by offering a stable, productive, and inexpensive labor force, a 'business-friendly' political climate with low or nonexistent corporate taxes, highly subsidized infrastructure (roads, power supply, and ports), and weak labor unions. Maquilas attract a young, predominately female, workforce, many of whom come from rural areas to seek stable employment.

Maquilas have provided an economic alternative to farm labor or unemployment for people throughout Central America, but their low wages and harsh working conditions have made them targets of criticism. For example, the National Labor Committee (NLC), a labor solidarity movement in the United States, brought to light labor abuses (including child labor, intimidation, and nonpayment of wages) in Honduran maquilas. The NLC produced a scandalous documentary called *Zoned for Slavery* in 1994, and in 1996, Charles Kernaghan, the NLC director, testified before Congress about some of the labor violations he had seen in Honduras. His testimony led to the public shaming of television celebrity Kathy Lee Gifford, who owned a clothing line that employed children in the Honduran maquilas that Kernaghan had visited. Following this affair, Central American maquilas became targets of international activist campaigns, including UNITE! and the United Students Against Sweatshops (Pine, 2008). Faced with foreign competition from China and Southeast Asia, wages in maquilas have not risen significantly. Since the 1990s, increased national and international monitoring of working conditions has led to some improvements.

The growth in the maquila sector was part of a broad strategy to diversify Central American economies, cutting down their reliance on export monoculture of traditional crops like coffee, bananas, and timber. In 1989, the International Coffee Agreement (ICA) was dismantled, leading to the deregulation of world coffee prices, which had been controlled by treaty since the 1960s. The end of the ICA introduced a new level of risk into the coffee economy, and countries like Guatemala and Costa Rica, which were highly dependent on coffee exports, sought to develop new export industries. Honduras, which had been a 'sleeping giant' in the world coffee market, became Central America's largest coffee producer in the late 2000s.

Tourism also became a high-growth industry in the 1990s. Costa Rica was the first tourist success story in the region, famous for attracting adventurous, environmentally oriented visitors to its beaches and rainforests. Nicaragua, Panama, and Belize have also become tourist hotbeds, and El Salvador, Guatemala, and Honduras have invested heavily in coastal developments to attract foreigners.

The common thread that connects maquilas, export agriculture, and tourism is that all three industries rely strongly on the US consumer market, and to critics, they recreated the patterns of dependency that marked the twentieth century. Viewed as one model of economic progress, neoliberalism prioritized GDP growth over more collective visions of social justice. Within the political sphere, a similar process of ideological narrowing took place. During the peak decade of neoliberalism (1994–2003), nongovernmental organizations (NGOs) became influential players in the political life of the region, filling the void left by the shrinking role of states in environmental policy, human rights, health, and labor issues, particularly in the countries in the region that were most dependent on foreign economic aid (El Salvador, Nicaragua, Honduras, and Nicaragua). NGOs tended to rely on international donors and foreign leadership, and, although they have led many important reforms around the region, they have been criticized for holding a somewhat narrow and opportunistic political philosophy, focusing their energies on single issues that can attract foreign funding, rather than systematic visions of social justice.

By the mid-2000s, the 'neoliberal experiment' had not created the broad based economic growth that its proponents had promised, and people around Central America began to call for changes that would stimulate the domestic economy and provide a more inclusive vision of social progress. A new form of antineoliberal politics emerged, most notably in Nicaragua and Honduras, where Presidents Daniel Ortega (elected in 2006) and Manuel Zelaya (elected in 2005) espoused a new form of populist nationalism, explicitly defining themselves as opponents of neoliberalism. Ortega and Zelaya both signed agreements to join the Bolivarian Alternative for the Americas (ALBA), an international trade agreement led by Venezuela and Cuba, which sought to provide an alternative to the neoliberal model of free trade, epitomized by the CAFTA-DR, the Dominican Republic – Central America Free Trade Agreement (signed in 2005), and the proposed Free Trade Area of the Americas, a plan to reduce barriers to trade across the Americas. Free trade, the central pillar of neoliberal policy, came to be defined as a new kind of imperialism, and movements like ALBA symbolized a rejection of neoliberal doctrine. In Honduras, Zelaya's entry into ALBA, along with an attempt to significantly raise the Honduran minimum wage, were viewed by the business community as a threat to the global competitiveness of Honduran industry. Zelaya's antineoliberal policies began a political crisis that ultimately led to a coup d'etat that forcibly removed him from power in June 2009.

Multiculturalism, Religious Change, and New Forms of Citizenship

Since the late 1980s, the politics of multiculturalism have significantly changed concepts of national identity and belonging in Central America. Throughout the nineteenth and twentieth centuries, groups that were ethnically, linguistically, racially, and/or culturally distinct from national majority were often stigmatized and subjected to official policies of discrimination. Indigenous people were targets of assimilation programs, exploitation, and violence and were sometimes seen as impediments to modernization and 'civilization.' By the end of the twentieth century, people around the world had come to embrace ethnocultural difference as a mark of democratic openness and tolerance. This change created new political spaces for cultural groups to make demands against the state. The era of 'multiculturalism' was exemplified by Rigoberta Menchú's 1992 Nobel Peace Prize and the United Nations' declaration of the years 1995–2004 as the first International Decade of the World's Indigenous People.

In Guatemala, the Pan-Mayan movement arose in the aftermath of genocidal war. The movement embraced Mayan languages, styles of dress, and religion, which had been suppressed or stigmatized for much of the county's history (Warren, 1998). Mayan activists gained influence in politics, calling for affirmative action programs and targeted development aid, forging strong alliances with international NGOs (Fischer and Benson, 2006). While the Maya are still subject to racial discrimination, indigenous activism has led to more inclusive notions of citizenship. At the same time, the government has used colorful, exotic images of Mayan 'authenticity' to brand itself to foreign tourists, using the recent shift toward cultural tolerance as a marketing tool. The new forms of cultural capital that have emerged within the tourist economy have generated complex questions about what it means to be Maya in multicultural Guatemala, and shifting notions of ethnic identity have become a topic of great interest for anthropologists.

Multiculturalism in Honduras has followed a somewhat different course. The Garifuna people, descendents of residents of the island of St. Vincent who were deported to Central America in the late eighteenth century, have developed a new ethnic consciousness over the past two decades (Anderson, 2009). The Garifuna, formerly called the Black Caribs, define themselves as both 'black' and 'indigenous,' and take part in political movements associated with indigenous rights and the Black diaspora in the Americas. The Garifuna have aligned themselves with other Honduran indigenous political organizations to make demands for land rights, often in opposition to tourist developments near their homes on the Caribbean coast. Like the Maya in Guatemala, the Garifuna have been used as a symbol of Honduras' cultural diversity in the county's attempt to attract foreign tourists. More broadly, the Garifuna have become part of the Honduran national imaginary as it recasts itself from a predominately mestizo society to a multiethnic nation.

Along with ethnicity, the relationship between religion and national identity has also undergone important shifts since the 1980s. Roman Catholicism was by far the dominant religion in Central America from the colonial period until the second half of the twentieth century, when evangelical Protestantism began an explosive period of growth. The rise of evangelical religion in the region began in Guatemala, where more than 60% of the population now identifies as protestant (O'Neill, 2010: p. 11). A similar pattern has taken shape in Costa Rica, Honduras, El

Salvador, and Nicaragua, which are all home to significant evangelical populations that have grown rapidly in the past few decades. Evangelical movements in Central America tend to embrace independence from top-down religious bureaucracies and have a flexible stance toward doctrine. As O'Neill argues, they have a certain affinity with neoliberal democracy, in that they celebrate the power of the individual to transform social life through moral behavior, eschewing more collective visions of social change. The evangelical turn is especially striking when viewed alongside the declining popularity of liberation theology, a form of Catholicism that was influenced by Marxist visions of social justice, which was quite influential in the peasant movements 1960s and 1970s. Whereas liberation theology and related forms of social Catholicism embraced collective political action, the new evangelical movements emphasize the power of the moral individual to bring about a better world. The popularity of evangelical religion has begun to feed back on the Catholic Church itself, where the Catholic Charismatic Renewal (CCR) movement has provided an alternative to the traditional Catholicism that involves spiritual healing, ecstatic prayer, and a direct relationship between the worshipper and divinity.

The politics of gender and sexuality are another dimension of social life that has undergone significant change since the 1990s. Women have taken on high-level political positions throughout Central America, with Nicaragua, Costa Rica, and Panama all electing female heads of state since 1990. In countries where manufacturing and the service-sector work have replaced agriculture, women have gained economic independence, often becoming the primary wage earners in households. The rising economic status of women has challenged cultural notions of masculinity, leading some men to "participate in alternate economies to earn the money and respect that is denied them within the current legal economy" (Pine, 2008: p. 33). Across the region, birth rates have fallen as women find work outside of the home and the demand for agricultural labor declines. Another notable change in gender politics has been the rise of LGBT identity around the region. As Florence Babb (2003) and Cymene Howe (2008) describe in Nicaragua, demands for sexual rights emerged within the broader discourse of multicultural tolerance in the 1990s. While LGBT groups continue to be targets of discrimination (particularly in Belize, where same sex sexual activity remains illegal) public awareness of sexual rights has certainly improved.

While the anthropology of Central America has widened its focus since the end of the 1980s, there are still some areas of social life that remain understudied. The contemporary livelihoods of indigenous groups like the Lenca, Pech, Jicaque, and Guaymí are not well known outside of their home countries. Few anthropologists have produced substantial ethnographies of elites or professionals, particularly in Costa Rica and Panama, the most prosperous countries in the region. In general, studies of the middle classes are far less common than studies of the poor, and there are relatively few studies of Central American education, media, and expressive culture. In general, scholarship on the region has focused on the broad themes of political economy, postconflict justice, ethnicity, religion, and the environment. There is good reason for this: In the United States and Europe, much of the academic interest in the region developed in response to the violence of the 1980s, and has been closely tied to activist movements. As the 1980s fade from view, new social changes have taken root throughout Central America, and we can look forward to new directions in social scientific studies of the region that will incorporate voices and viewpoints from an increasingly global community of scholars.

Abstract

Mexican anthropology, long wedded to a national modernization project that required 'backward' indigenous cultures to assimilate culturally, began distancing itself from the state after 1968. Thanks to renewed international dialogue, Mexicanists – both national and foreign – have critiqued political and economic power relations, revalorized ethnic identity and agency, and deconstructed Mexican modernity by questioning the consistency and locus of national identity within official boundaries. New studies of migration, cities, territorial claims, the state, media, and language embody these paradigm shifts. The older, community-centered tradition of Mesoamerican studies has also reinvigorated its Boasian roots with contemporary cultural and ontological theory.

The Indigenista Legacy

Mesoamerica (comprising most of Mexico, Belize, and Guatemala) was the most heavily populated region of pre-Columbian America. Mexico's cultural heritage – including major archaeological sites and some 60 indigenous languages still spoken to varying degrees – has attracted anthropological attention from the government and foreign researchers since the nineteenth century. Now the country has a globalizing, sometimes violent economy, one of the world's largest cities, and a population of 115 million – 15 million of whom identify as indigenous (once again the most in the western hemisphere). Consequently it is a major site for studying modernity, tradition, sociopolitical change, and *mestizaje* (cultural dislocation and recombination), and it is impossible to talk about the anthropology *of* Mexico without analyzing the impact of anthropology *in* Mexico ever since the dawn of the discipline. Turn-of-the-twentieth century foreign sociocultural anthropologists who had a major impact included the Berlin school of ethnology's Konrad Theodor Preuss and the founder of modern American anthropology, Franz Boas (Columbia University), followed in the 1920s by Robert Redfield (University of Chicago). Yet these men all depended on Mexican interlocutors, some of whom also influenced anthropology's development in Mexico and beyond.

When Boas set up the International School of American Archaeology and Ethnology at Mexico's National Museum of Anthropology during the 1910 Revolution, about 15% of the country spoke an indigenous language (vs about 5% now). As a historicist and cultural relativist, Boas was primarily interested in documenting that diversity and the prehispanic legacy. However, to technocrats eager for Mexico to join the top tier of developed nations, that same diversity entailed social, economic, and political burdens that social anthropology ought to ameliorate. They also wanted archaeology to build the historical legitimacy of a state far more taken with France and the US than the communal agrarian societies of the ancient past and indigenous present.

Boas's student Manuel Gamio initiated postrevolutionary Mexican anthropology in the 1920s, and for 40 years his successor Gonzalo Aguirre Beltrán, *indigenismo's* central intellectual and administrator, directed the mission of assimilating 'backward' indigenous communities into dynamic multiethnic regions from the Instituto Nacional Indigenista (INI), while the Instituto Nacional de Antropología e Historia (INAH) managed the nation's cultural heritage (cf González y González, 1997). However, after the government crushed the 1968 student movement, the legitimacy of official institutions eroded. Guillermo De la Peña (1999) describes the subsequent transformation of nearly all Mexican sociocultural anthropology and compares it to other Latin American models (2005). Revisionism rocked the discipline as disaffected young scholars engaged Marxism and structuralism to consider indigenous historical agency and cultural dynamism. As Manchester social anthropologist John Gledhill put it,

> there is a fundamental difference between an anthropology that is about people and the worlds of meaning that they construct through experience, action and social interaction – always within a framework of evolving power relations – and an anthropology that is about how reified 'cultures' themselves 'live' and 'die'. For much of its history, 'what they call Mexican anthropology', to revisit the critique of the generation of 1968, was an example of the latter kind of anthropology. The strong concern of national anthropologists for practical issues of social welfare is perhaps the side of that old project which it is still worth recuperating (in a less authoritarian and paternalist manner).
>
> (2008: 18)

In addition to this agenda, well mapped by José Luis Escalona, another worthwhile legacy of Aguirre Beltrán is the ongoing vitality of regional studies, as evidenced in the work of De la Peña, Eric Van Young, Daniel Hiernaux, and early Claudio Lomnitz (1992), among others.

Still, the INAH carries on and the INI's twenty-first century neoliberal heir, the Comisión Nacional para el Desarrollo de los Pueblos Indígenas, has at least a shadow of its forebear's role in rural development. The INAH project *Etnografía de las regiones indígenas de México en el nuevo milenio* (e.g., Millán and Valle, 2003) exhibits an ongoing concern with Mesoamerican social structure, community organization, ritual territoriality, identity, interethnic relations, religious norms, and migration, as do the heirs of large community-centered projects run by Harvard, Chicago, Tulane, and other US universities in the

1950s and 1960s (e.g., Evon Vogt's *Zinacantan* and Monaghan, 1995) (see Section Community Studies below).

Interdisciplinary and International Connections

Interdisciplinary relations are key to understanding sociocultural research in Mexico. Because of anthropology's historical importance to the national modernization project, sociology is less institutionally prominent than in the United States or South America, excepting a few major institutions like the Universidad Autónoma Metropolitana-Iztapalapa (UAMI), the Universidad Nacional Autónoma de México (UNAM), and El Colegio de México (Colmex) (plus the mass-mediated commentariat). However, this permitted relatively unfettered sociologists (many of them 1970s Argentinian political refugees) to employ more contemporary theory and contribute original research. Historians have enjoyed the greatest prestige and much social anthropology, influenced by Eric Wolf and others, seeks to take a historical approach to power, even as most university and graduate programs allow almost no interdisciplinary study.

Not only are disciplinary boundaries not the arbiter of anthropological relevance, but shared concerns have jumped the fences between 'subfields' (which raises doubts about using them to organize this article except insofar as institutional boundaries themselves provoke new ideas). Moreover, defining a 'national tradition' is complicated by anthropologists' diverse geographical origins, sites of training, and fieldwork locations. With *indigenismo* fading out after 1968, more Mexican anthropologists won federal support for pursuing PhDs, fieldwork, and research networks outside Mexico or for in-country training in international-level doctoral programs with broad theoretical agendas. Here the Centro de Investigaciones y Estudios Superiores en Antropología Social (CIESAS, www.ciesas.edu.mx), UAMI (www.uam-antropologia.net/index.php?option=com_content&view=article&id=82:publicaciones-recientes&catid=9&Itemid=495), Universidad Iberoamericana (www.ibero.mx/web/site/tpl-Nivel2_pos.php?menu=mgPosgrado&seccion=d_antropologiaSoc), Colegio de México (http://ceaa.colmex.mx/index.php/informacion-academica/218), and Colegio de Michoacán (www.colmich.edu.mx/index.php/docencia-cea/planta-docente) stand out. Still, in part because of funding limits most Mexican anthropological fieldwork remains in-country, with only a handful of programs like the Colmex's Centro de Estudios de Asia y África sending students beyond the Americas. More importantly, anthropology's post-1968 concern with power, political economy, and social justice in Mexico should continue as long as the country confronts the dilemmas of uneven development in both urban and rural contexts.

The History of Anthropology and Nation Building

Taking account of the international dynamics in a period of increasing diversification, the Antropología del Sur initiative, identified with Esteban Krotz in Mexico and the late Robert Kemper in the US, drew on Immanuel Wallerstein to substitute a global North–South over East–West analysis of the discipline's development. It has honed a critical, postmodernization – if at times staunchly antipostmodern – Mexican anthropology (Krotz, 1997; Gledhill, 2011).

Some historians of Mexican anthropology are now revising post-1968 revisionism. Engracia Loyo and more recently Elsie Rockwell (2007) have described the central role of primary education in revolutionary state formation. Reappraising *indigenismo*, they have rediscovered progressive aspects of its rural education programs even as they keep questioning the revolution's prime directive to assimilate ethnic minorities to the mestizo project. Their legacy includes Marco Calderón's work on revolutionary-era educational experiments; Alexander Dawson on imaginaries of the indigenous; Emiko Saldívar's ethnography of waning *indigenista* practice; Stephen Lewis, who has collaborated with Mary Kay Vaughan, the preeminent historian of intellectuals and the state in Mexico; and, inspired by Florencia Mallon's notion of nineteenth century popular liberalism, Ariadna Acevedo on popular constructions of citizenship (see Calderón, 2012, for many of these authors). Parallel to education research is the work of historians of science like Mechthild Rutsch, Laura Cházaro, Miruna Achim, and Frida Gorbach on the role of scientific apparatuses (from measuring instruments to museums) in constructing Mexican national and racial identities.

Political Economy, Ecology, and Brokerage

Central to Mexican anthropology's concerns with regional organization and the state is brokerage, possibly its most consistent theme ever since Eric Wolf's classic formulations (1956). Wolf's influential materialist synthesis emerged from collaborations with Mexican researchers, especially Ángel Palerm, who went on in the 1970s to develop a neo-evolutionist Marxist cultural ecology focused on the relationship between political power and control over natural resources (particularly land and water). Even leading non-Marxists like Norman Long, whose social anthropology has emphasized small group interactions in transnational labor contexts, also rely on Wolf's basic model. Characteristically, in both backward rural areas and urban communities dependent on clientelistic connections to political and economic authorities, access to resources is mediated through the *cacique* or boss (see the work of José Eduardo Zárate) and the ritually inflected forms of land tenure, historical memory, and social organization in which power is materialized (e.g., Jorge Uzeta's research on Atarjea, Guanajuato). Since the 1960s, Paul Friedrich's Michoacán corpus (1986) has set the standard on *caciquismo* and violence, and James Greenberg's ethnographies of indigenous Oaxaca (1989) continue addressing Friedrich's and Wolf's concerns. Fernando Salmerón's review article on the *caciquismo* literature (1984) is still valuable as is Wil Panster's more recent volume (2005).

Political economy and hegemony have remained key concerns for other scholars influenced by Wolf, like William Roseberry, Andrew Roth, Gavin Smith, Juan Pedro Viqueira, and Josiah Heyman. In particular, Roseberry's early work on commodity chains and his later incursion into culture theory (1989) inspired younger Mexicanists like Ricardo Macip Ríos and Casey Walsh. Anthropological historian Paul Eiss (2010) has brought new spatial and temporal perspectives to

political economy, ethnic identity, and historical memory in Yucatán.

More broadly, although the country is now 80% urban and 90% mestizo, the crisis of *ejidos* (collective land grants) and indigenous communities, especially in rural southern and central Mexico, still commands popular and scholarly attention because of the centrality these forms of land tenure have to the revolutionary project and national identity. After the Ejército Zapatista de Liberación Nacional's antiglobalization rebellion of 1994, multiculturalism as a basis for territorial and human rights claims became a major line of research (Sieder et al., 2002). This orientation undergirds activist studies of social movements by figures like Víctor Toledo who emphasize indigenous ecological sensibilities. David Barkin and Hernán Salas use *la nueva ruralidad* to emphasize globalization's role in placemaking (Torres, 2012). Others like Héctor Díaz Polanco combine traditional Marxist class analysis with attention to ethnicity and regional autonomy initiatives.

Recent ethnographies analyze new indigenous regional sovereignty claims (Liffman, 2011), critique the wave of transnational mining activity (Claudio Garibay), and study 'food sovereignty' opposed to genetically modified transnational crops, especially maize (Elizabeth Fitting). The current proliferation of private security forces, community *autodefensas*, and *narco* shadow states proclaiming autonomy and justice have darkened the optimistic pictures that emerged after 1994. Instead, scholars inspired by Das and Poole (2004) highlight uneven geographies of power on the margins of the neoliberal state (e.g., Froylán Enciso http://nuestraaparenterendicion.com/index.php/blogs-ok/weary-bystanders). Legal anthropology has gone beyond examining juridical processes for indigenous populations to question the state apparatus itself (Sierra, 2004; Sieder, 2013).

Within the post-1968 critique of *caciquismo*, state power and neoliberalism, drug trafficking is one of the most gripping subjects. Carlos Flores's project *Historias de polvo y sangre* traces drug smuggling in Tamaulipas back to the 1940s and finds links to the highest echelons of the Mexican government, whereas Salvador Maldonado's historical ethnography traces drug production in Michoacán to postrevolutionary modernization programs that failed because (nonillicit) brokerage between rural communities and the state broke down. Recent antecedents are Luis Astorga's work on *narcotraficantes* (2007) and Lomnitz's broader volume on corruption (2000). Narcoethnography is also traceable to earlier studies of urban violence and gangs (*bandas juveniles*) by Rosanna Reguillo and Néstor García Canclini.

Even though Marxism was highly influential here, Macip describes a 'watermelon' strategy since the rise of neoliberalism: leftist anthropologists discovered that turning 'green on the outside' was a way to survive institutionally, as at the Universidad Autónoma Chapingo. Indeed, a number of them became honeydews through and through. Recent work seeks a synthesis of political ecology, cultural property, and science and technology studies (STS), updating Palerm's cultural ecology tradition. Casey Walsh studies the hydraulic issue in northern Mexico, Andrew Mathews takes an innovative approach to forestry, Molly Doane takes on the contradictions of environmental governance, and Cori Hayden has pioneered bioprospecting research. Akin to STS's interest in risk, disaster studies like the CIESAS project inspired by Kenneth Hewitt and Ulrich Beck and directed by Virginia García Acosta critique state development projects. The approach has overcome the false naturalism and randomness once attributed to disasters and considers local interpretations as well, as in the opposition to mining, hydraulic, and wind energy development (Howe, 2014).

Indigenous Identity and Social Movements

Many of the aforementioned approaches echo the social movements literature developed by Jorge Aceves and Alain Touraine in the 1970s and subsequently advanced by Joe Foweraker and Ann Craig. Instead of fixed cultural identities, it found situated strategic alignments even as images of timeless Mesoamerican cultural continuity and resistance proliferated in the 1990s, thanks to Guillermo Bonfil's seminal *México profundo* (1996[1989]) and new political actors' growing reliance on identity politics.

The interest in identity ranges from conservatives who inscribe folklore traditions into the national cultural heritage to leftist sympathizers of Zapatista-inspired movements that demand national policies to benefit the rural sector and defend the country's cultural and ecological sovereignty. Both approaches are haunted by Gledhill's pungent observation that "almost all the assumptions that anthropologists of varying theoretical persuasions had made about the conditions that would foster reproduction of indigenous ethnicities or 'assimilation' in the form of mestizoisation have eventually been falsified by history" (2008: 5). Constructivist or antiessentialist approaches like Gledhill's and the social movements literature in general point to the fact that "the 'identities' that people use do not necessarily correspond to anthropological constructions of 'culture' and 'ethnicity'" (2008: 11). However, another legacy of *indigenista* authoritarianism is the apparently scant awareness or concern among some academics that such observations can erode the legitimacy of grassroots movements (see Briggs, 1996). Still, Gledhill himself takes a broad view:

> In seeking to revalorise their traditions and culture, even in a manner that distorts the historical record, indigenous activists have opened up national debates and challenged entrenched ideologies more effectively than academic anthropologists. This raises important questions about what the future agenda for academic anthropology should be in countries like Mexico.
> (2008: 15)

Indigeneity studies by authors like Michael Kearney and Federico Besserer build on Kearney's classic article with Carol Nagengast (1990) to examine how international migration foregrounds previously unmarked cultural identities, even as its globalizing nature blurs the previously national focus of Mexican anthropology.

Despite the attention paid to identity politics – and widely read studies on gender and indigeneity by researchers like Aída Hernández and Lynn Stephen (Speed et al., 2006) – at least

within the formal bounds of anthropology, gender and queer studies in Mexico remain limited (but see Prieur, 1998). The exceptions are often in cultural studies and sociology, such as the Colmex's Programa Interdisciplinario de Estudios de la Mujer and the UNAM's Programa Universitario de Estudios de Género. The larger exception within anthropology is the research on labor and violence, where *masculinidades* is a dynamic approach emerging from international dialogues (Gutmann, 1996).

Popular Religiosity

Akin to the social movements literature is the burgeoning work on popular religiosity, especially Latin America's rising Protestant wave. This research can be traced back to projects that emerged from the regional studies tradition in the 1980s. Most prominent were Elio Masferrer's (2000, 2004) Asociación Latinoamericana para el Estudio de la Religión, CIESAS's Religión y Sociedad en el Sureste (under well-known regionalist Andrés Fábregas), and the pan-Latin American Comisión para el Estudio de la Historia de la Iglesia en América Latina y el Caribe (CEHILA) under María Alicia Puente Lutteroth, which included Mexicanists María Eugenia Ugarte and Víctor Gabriel Muro (a liberation theology scholar). Currently the Red de Investigadores del Fenómeno Religioso en México (www.rifrem.mx/?page_id=11) coordinates much research and publication. Work influenced by Masferrer's ex-student Carlos Garma stresses Protestantism's endogenous logic over its foreign antecedents, thereby opposing David Stoll's earlier critique of it as an imperialist import. Without reducing new religious phenomena to North American conspiracies, cross-border connections are key (Odgers and Ruiz, 2009). Other topics include the expulsion of Protestant minorities from indigenous communities (Rivera et al., 2005), popular Catholicism, New Age or *la Nueva Mexicanidad* (Argyriadis et al., 2008), and the intersections of religion, gender, and power in religious movements, studied by Elizabeth Juárez Cerdi. As introductions, the *Atlas de la diversidad religiosa en México* (De la Torre and Gutiérrez, 2007) and its companion volume (Hernández and Rivera, 2009) condense basic demographic information on minority religions.

Community Studies

The concern with power, region, movements, and mutable identities reacted against community studies dating back to Robert Redfield and his research partner Alfonso Villa-Rojas. Nonetheless this literature, typically focused on indigenous forms of communal land tenure and social reproduction via civil-religious cargo systems, is alive and well where it has incorporated new theoretical perspectives. Catherine Good (Broda and Good, 2004) exemplifies long-term fieldwork in indigenous central and southern Mexico, updated with political and feminist concerns. Kinship research by scholars like Hugo Nutini and his ex-student David Robichaux also evince the tradition's fine-grained ethnography. Scholars influenced by Claude Lévi-Strauss, the more recent (and already morphing) ontological turn identified with Eduardo Viveiros de Castro, and models of partible personhood elaborated by Roy Wagner and Marilyn Strathern have done important work on indigenous communities. These include analysts of the myth, ritual, cosmology, art and history of Otomís (Jacques Galinier), central Uto-Aztecan cultures (Jesús Jáuregui), Huichols (Johannes Neurath), Guerrero Nahuas (Aline Hémond), Mixtecs (John Monaghan), and Tzeltal Mayas (Pedro Pitarch, whose 2010 book draws on Wagner to recast interethnic relations from an indigenous ontological perspective). Ben Feinberg has turned the tradition on its head with his experiments in literary representation and demonstration of how Mazatec shamans' use of space confounds closed models of community and region.

Linguistic Anthropology

Despite the diverse fieldsites where linguistic anthropologists (many of them US-trained) have worked since the 1970s, they often share approaches inspired by semiotician CS Peirce and literary theorist Mikhail Bakhtin. Jane Hill has contributed both formal linguistic analyses and broadly anthropological work, originally with Nahuatl speakers in the Sierra Norte de Puebla. John Haviland's work in Chiapas spans the linguistic marking of social status to legal anthropology and most recently the interface between Tzotzil Mayan speakers and sign-language users. John Lucy has updated Benjamin Lee Whorf with his examination of Yucatec Mayan language and thought. William Hanks has a broad ethnographic and ethnohistorical corpus on Yucatec, expanding the purview of deixis to link language, geographical space, cosmology, and social hierarchy. Teresa Carbó's discourse analysis has taken formal structural description (the central concern of Mexican linguistics) to an ontological turn. Among the emerging generation of linguistic anthropologists, Hilary Parsons Dick (2011) has published on Bakhtinian chronotopes of movement in Spanish, with a focus on migration.

Many scholars (e.g., Nancy Hornberger) continue to focus on indigenous language revitalization in Latin America, especially where Amerindian speech and writing still have multiple socioeconomic and political functions. However, Shaylih Muehlmann (2013) shows how Cucupá youths' Rabelaisian mistranslations for nonspeakers subvert the official reliance on native language use as an ethnic marker – for them a vestige of *indigenista* paternalism and national patrimony discourses that neoliberal multiculturalism has only resuscitated.

Visual Anthropology

Visual anthropology highlights the growing attention paid to indigenous forms of representation and agency. Early promoters from other anthropological subfields like Ricardo Pérez Montfort, Scott Robinson, Margarita Dalton, Victoria Novelo, and François Lartigue helped establish CIESAS and the UAMI as centers for ethnographic media in Mexico. Interdisciplinary inspiration came from the prominent historian of

photography, John Mraz, and the historian of Latin American cinema, David Wood. The new generation includes Deborah Dorotinsky (UNAM-Instituto de Investigaciones Estéticas), Antonio Zirión (UAMI), Carlos Y. Flores (Universidad Autónoma de Morelos), and the German scholar Axel Köhler. Köhler, Flores, Carlos Antaramián, Laurel Smith, Byrt Wammack Weber, Erica Wortham, and Gabriela Zamorano not only theorize local agency in media production but collaborate with their subjects in filmmaking, addressing both ethnic and gender issues, often in rural southern Mexico but also in urban and foreign settings (http://nmai.si.edu/explore/film-media/native-media-topics/mapping-mexican-media/). This reflects the influence of the University of Manchester's Granada Center for Visual Anthropology, Deborah Poole's (1997) pioneering visual anthropology work in Peru and her deconstruction of race and ethnicity in Oaxaca, as well as Faye Ginsburg's leadership of New York University's Graduate Program in Culture and Media. Jesse Lerner's 'false documentary' and other experimental approaches have influenced recent Mexican work, including Sandra Rozental's *Piedra Ausente/Absent Stone*, a film (and forthcoming book) addressing the instability of national patrimony as the state expropriates and formerly docile subjects reappropriate it.

Urban Space

Traditional urban anthropology, insofar as it assumed *barrios* were structured communities, had reflected *indigenismo's* obsession with coherent pueblos and the *grandes problemas nacionales* of modernity and modernization. This stemmed from a more fundamental reliance on Émile Durkheim's image of organic solidarity instead of Georg Simmel's urban anonymity. The community-oriented approach yields convincing results where rural groups actually manage to establish solidary urban colonies, as pioneered in the work of Larissa Lomnitz and carried forward in studies of planned neighborhoods (e.g., Claudia Zamorano). But inspired by Michael Warner's notion of shifting counter-publics, there is now a complementary image to the persistent community in urban Mexico (Duhau and Giglia, 2008). Linked to urban research predicated on neoliberal anomie and uncertainty are examinations of violence, another area where sociologists are more prominent than anthropologists. Arturo Alvarado (2012) engages the historical sociology of Diane Davis in his work on policing in the Mexico City metropolitan area.

Previously economists and sociologists (e.g., Brian R. Roberts) had examined demographic and political-economic contexts shaping urban space. Other senior researchers in the urban field include Daniel Hiernaux and Raúl Nieto of the UAMI, whose notions of spatial appropriation contextualize urban conflicts. Also at the UAMI is Néstor García Canclini (2001), whose work dialogues with the global cities scholarship of Saskia Sassen. But central to this article, the UNAM-based scholar and jurist Antonio Azuela's landmark work (1999) brought the social relations behind real estate markets into urban anthropology. His interest in patrimony – the inalienable possession of land – dovetails with contemporary indigenous struggles. It also resonates with Elizabeth Ferry's updating of a Marxist approach to silver mine labor in terms of Annette Weiner's "paradox of keeping-while-giving" such possessions. Azuela emphasizes what Laura Roush (2014) dubs "the protection racket model of urbanization": a basic tactic for the great majority who cannot get housing through conventional market transactions is to exploit the *amparo* (injunction or staying order) and resort to clientelism and other extralegal measures to obtain infrastructure development and legalize squatting.

Cristina Mejorada Sánchez and Elías Huaman have followed Azuela's lead, as have more recent US-trained scholars like Roush and Alejandra Leal. Leal's work on the gentrification of Mexico City's *centro histórico* gives proof that Mexican urban anthropology is becoming a channel for inquiring into the nature of the nation, liberalism, crowds, identities, and Derridean self-constitution via the absent Other. In this case, that Other entails Roush's "sinister broker who sells the *amparo*" and the spectral working class 'pueblo'. The yuppie wave may be displacing them but still they threaten to 'invade' the 'purified' urban core made safe for the rule of law.

Migration and (Post-)Borderology

Migration studies emerged from sociological concerns with labor and demography to examine urban phenomena, transnational indigenous movements (Kearney, 1996), and the questionable coherence, boundedness, and sufficiency of the nation-state as a category of analysis. Key literature includes Roger Rouse's seminal article on the relationship between Mexican home communities and their migrant offshoots in the United States (1991), long-term anthropological projects like Gail Mummert's (1999) and Douglas Massey and Jorge Durand's more strictly sociological corpus. Mummert's recent work, among others, examines how the threat of deportation and ad hoc household arrangements in the diaspora transform kinship, gender, and sexuality (Cantú, 2010).

Related to migration studies (primarily by location) is 'borderology' – originally identified with cultural studies – by such figures as José Manuel Valenzuela of the Colegio de la Frontera Norte. Emergent approaches leave behind the earlier, more optimistic Chicano imaginary, which envisioned an interstitial third country around *el bórder*. A more sober assessment, reaching back to Andrés Reséndez's border history and Pablo Vila's emphasis on prejudice, stereotyping, and other kinds of cultural friction, stresses nation-states' constraints on classes of people who cannot move as freely as transnational capital, especially since 11 September 2011.

Also contesting previous generations' confinement of Mexicanists within national boundaries is the work of Claudio Lomnitz and his students who have undertaken an anthropology of the state and the national space. Lomnitz (2001) manifested this agenda in his rejoinder to Bonfil's *México profundo* and his analysis of the temporality of 'crisis' engendered by the fiscal crunch of 1982. This revision inverts standard center-periphery models because it explores the

edges of countries and marginal spaces within them as sites where national identity is produced rather than diluted, even as officialdom attempts to erase or assimilate such impurities. Emergent work includes Leal's and Roush's urban ethnographies and Rihan Yeh's analysis of Tijuana as a site of state operations that inflect different publics' efforts to articulate national identities. Trevor Stack's binational ethnography of Mexican local intellectuals' conceptions of citizenship parallels such concerns.

Looking at the state itself, Josiah Heyman's corpus has focused on border enforcement apparatuses. Mateo Taussig's work on Immigration and Naturalization Service (INS) detainment facilities represents another approach to critical immigration studies, influenced by Giorgio Agamben. Lomnitz's transnational approach to Mexican national identity is explicit in his study of the revolutionary-era Flores Magón brothers, who inhabited both sides of the border as they forged a new ideology of collective belonging to the land (2014). That underscores this article's overall point: the growing academic recognition of popular agency in language and media, the geographical margins, and urban areas, distanced from *indigenista* anthropology's focus on the rural Mesoamerican core where national mestizo culture would one day domesticate otherness.

Acknowledgments

My thanks to the editors of this volume, my colleagues at the Colegio de Michoacán and Rice University for their generous suggestions. My apologies to those scholars whose important work was overlooked or could not fit into this highly condensed and partial format. A more complete bibliography is available on request.

Americas, Sociocultural Overviews: North America, Native Americans

Russell Thornton, University of California, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

An overview of Native Americans north of Mexico is provided, including characteristics of Native American societies and cultures, aspects of Native American history – especially governmental policies aimed at assimilating Native Americans – and the contemporary situation of Native Americans in the United States and Canada. Particular attention is given to Native American origins, aboriginal population size, population decline following the arrival of Columbus, and recent population recovery and current demographic situation. The study of Native Americans is also considered, as it was important in the development of anthropology in North America and elsewhere.

Origins

Scholars have for some time generally accepted the notion that *Homo sapiens sapiens* – those who became the Native Americans – first arrived in the Western Hemisphere from the Asian continent. In this respect, they acknowledge the biological affinities between Native Americans today and peoples in eastern Asia. There was also general agreement that *H. sapiens sapiens* arrived via the Bering Land Bridge (or its western coast), which has existed at least four times in the past 70 000 years. The issue was not so much how *H. sapiens sapiens* arrived, but when. The conservative view, based on clearly dated human skeletal remains, is that humans arrived only around 10 000 years ago; the liberal view, based on less clearly dated human skeletal remains, as well as other types of evidence, e.g., tool making traditions, language, archeological sites, is that humans have been in North America at least twice as long, if not considerably longer. Scholars have also revised their thinking as to how humans arrived in the Western Hemisphere, initially and/or subsequently. Another migration route gaining increasing acceptance is a maritime one, whereby humans migrated along the coast and thus around the edges of large glaciers that covered much of the northern part of North America at that time period. Some have even suggested an arrival from the Iberian peninsula! It is generally accepted now that there was not just one migration, or even just two: the first, the ancestors of American Indians; and the second, the ancestors of Inuit (Eskimos) and Aleutian Islanders. Most scholars would now accept the notion that there were at least three migrations: one, ancestors of most American Indians; two, ancestors of Athabascan American Indians; and, three, ancestors of Inuit and Aleuts. There is even acceptance of possible other migrations, as evidenced by the controversy and speculations surrounding 'Kennewick man.'

Some of these migrations may have come from areas other than Asia. Confusing the scholarly study of arrivals and their timing is the idea of continued contact between peoples of the Pacific Rim following migrations. Posed to provide clarification of migrations, dates and affinities are developing techniques of analysis, e.g., DNA. Future generations of scholars will provide future answers and, undoubtedly, future controversies. It is clear, however, that what is emerging is a complex and dynamic picture of the peopling of the North American continent.

Early Native Americans

However and whenever, and however many separate times humans arrived in the Western Hemisphere before the late fifteenth century, they eventually developed elaborate and diverse societies and cultures. They, for example, developed a remarkable variety of material cultures, ones obviously shaped by the environments in which they lived and by how they exploited these environments. Some were foragers, exploiting different facets of their environments for food, clothing, shelter, etc., during different seasons of the year. Others were hunters, of deer and buffalo, particularly, but earlier of mammoths, mastodons, and giant sloths; or they were fishers, for example, of salmon in the Pacific Northwest and Alaska. Yet others were maritime hunters of whales, seals and walruses. Many American Indians became agricultural peoples, typically growing maize by 1492 – which diffused northward from present-day Mexico – but also other foods (e.g., squash and beans), along with maize, in the Southwest and East, or camas in the Pacific Northwest.

Cultural life also became rich. Multiple rituals and religions developed and flourished, along with diverse patterns of kinship and marriage, political organization and governance, and practices whereby youths became adults. Europeans considered many of these to be exotic, and compared them to ones they were familiar with in Europe and elsewhere in the world. Varied patterns of political organization and governance developed as well. For example, tribal patterns of organization diverged widely, ranging from small, extended kinship systems to triblets to tribes to confederacies and chiefdoms. Probably, the most spectacular Native American peoples north of present-day Mexico – from the European point of view – were the chiefdoms in Florida and the Southeast to the Mississippi River described by the chroniclers of the explorer Hernando de Soto, whose expedition traveled the area from 1539 to 1543. These were large, dense settlements controlled by rulers, one of whom was the well-known 'Lady of Cofitachequi' (from present-day South Carolina). These chiefdoms soon declined following the arrival of European explorers, probably mainly from epidemic diseases brought by the Europeans. Some, however, such as Cahokia, across the Mississippi River from present-day St. Louis and the largest city in the Western Hemisphere north of Mexico, had reached their zenith prior to European contact.

Perhaps a close second from the Europeans' definition of spectacular Native American peoples were the pueblos of the Southwest, described at about the same time as were the Florida chiefdoms by the explorer Hernando Coronado, and located generally along either side of the Rio Grande River. Other regions of aboriginal North America had Native American civilizations that impressed Europeans to some degree, although Europeans were decidedly unimpressed with some Native American societies and cultures they encountered.

Size and Distribution throughout North America

Native American populations, in the form of hundreds of distinct peoples, were distributed widely throughout North America *c.*1492.

Aboriginal Population Size

Scholars continue to debate the size of the Native American population present in North America north of Mexico *c.*1492, and thus also the magnitude of population decline that began soon after European arrival and continued to about 1900. James Mooney (1928) of the Smithsonian Institution formulated the classic estimate of aboriginal population size at, as he expressed it, "first extensive European contact": he asserted that there were some 1.153 million Native Americans north of the Rio Grande River. Subsequent scholars have offered both slightly lower and far larger population estimates, ranging from Kroeber's (1939) 1.025 million to Dobyns (1983) 18 million (for north of Mesoamerica, an area including northern Mexico as well as the United States, Canada, and Greenland). The estimate I formulated and continue to use is 7-plus million, composed of some 5 million for present-day United States, and some 2 million for Canada and Greenland.

Distribution

Populations were not distributed evenly, however. For example, Kroeber (1939) used the concept of 'cultural areas' to divide Native American groups north of Mexico into areas sharing similar cultural traits as adaptations to similar environments. According to him, the largest populations were found in the Southeast and California; the largest population concentrations were found in the Pueblo and Lower Columbia regions (Kroeber, 1939, Table 8). More recently, Ubelaker (1988) argues that the largest area populations were found in the Southeast and the Northeast.

Impact of European Contact

Contact with Europeans following the beginning of their extensive colonization of the Western Hemisphere after 1492 brought fundamental changes to native populations, and their societies and cultures. During the 1990s, 'holocaust' emerged as the metaphor to view the population collapse of Native Americans accompanying European expansion into this hemisphere (Thornton, 1987). Likewise, this 'holocaust' has emerged as crucial to understanding the full impact of colonialism upon Native Americans, and their subsequent social, cultural, biological, and even psychological changes. Native American societies and cultures, and Native Americans as biological and psychological entities were all impacted by demographic collapse after 1492.

Tribal Decimation and Relocation and/or Concentration

During the first four centuries following initial European contact, virtually all Native American groups experienced population decimation, and relocation and/or concentration, to some degree. Early relocations were sometimes voluntary, as American Indians moved westward to escape encroaching Europeans on America's east coast. This in turn produced conflicts with other American Indians as they were pushed farther west by the immigrant Indians. Subsequently, however, relocation became the official policy of the US government.

Native American population size in the United States and Canada declined for some 400 years, reaching a nadir population around the beginning of the twentieth century of perhaps only 375 000. The causes of the population decline, of course, were epidemics and other diseases introduced from Europe and Africa, e.g., smallpox, the plague, measles, forms of influenza, whooping cough, cholera, typhoid, diphtheria, scarlet fever, yellow fever, malaria, and various sexually transmitted diseases. European, Euro-American, and American colonialism in all its forms also contributed to Native American population reduction through warfare and genocide, relocations, and destruction of economic systems as well as the association of disease with all of these. Important, too, in the equation was the inability of Native American populations to recover from population losses as their societies and cultures were undermined by colonialism.

Accompanying this decimation were further patterns of population relocation and/or concentration, typically onto reservations. The largest pattern of population relocation occurred as official US government policy in the first half of the nineteenth century, whereby large populations of Indians in the Southeast – primarily the Cherokee, Chickasaw, Choctaw, Creek, and Seminole – were removed to lands west of the Mississippi River, lands which were designated Indian Territory and eventually became the eastern half of the state of Oklahoma in 1907. Other tribes were removed into what became the state of Oklahoma (named after Oklahoma Territory, the former western half of the state) as well, particularly ones from other parts of the Southern and Western Plains, the Northern Plains, and the so-called Old Northwest, around the Great Lakes.

US government troops, especially following the United States Civil War which ended in 1865, were used in particular to subjugate Native Americans by forcing them onto reservations in Oklahoma Territory, Indian Territory, and elsewhere in order to contain them and reshape their ways of life. American Indian struggles against such repression included new spiritual movements such as the Ghost Dances of 1870 and 1890, and the Peyote Religion, which arose among many Indian peoples. However, struggles also culminated in infamous massacres,

e.g., at Sand Creek, Colorado; Fort Robinson, Nebraska; and Wounded Knee, South Dakota.

Tribal or Individual Indian

After establishing a reservation system for American Indians, the US government soon began to undermine the integrity of many Indian lands when it saw the reservation system as 'not working' to 'civilize' Indians. From the late nineteenth century into the early twentieth century, policy was introduced to allot parcels of land on some reservations, and in Oklahoma and Indian Territory to individual Indians, thereby eliminating many reservations. A reduced reservation pattern therefore emerged, with most remaining reservations being in the west and representing only small remnants of former lands.

The idea was that Indians were to become individual Indian citizens on privately owned parcels of land. This culminated in the Citizenship Act of 1924, which made all American Indians in the United States citizens for the first time and gave them full voting privileges. 'Leftover' or 'surplus' lands were then 'opened' to claims by non-Indians. Accompanying allotment were larger political and corporate desires for American Indian lands. The decades following the period were characterized by frauds whereby individual allotments ended up in the hands of land barons, speculators, and corporations, as Debo (1940) has shown for the Cherokee, Chickasaw, Choctaw, Creek, and Seminole in Oklahoma; and as Meyer (1994) has shown regarding the White Earth Reservation in Minnesota.

American Indian tribal life was undermined greatly by allotment. Tribes able to retain tribal land in the form of reservations survived as tribes and as Indians better than those that were not able to do so. This included Indians on the Plains and in the west and southwest. In 1934, the Indian Reorganization Act was enacted, acknowledging that an Indian tribe had 'rights to organize for its common welfare.' The Act served to codify tribal governments under the all too watchful eyes of the Bureau of Indian Affairs. And, in turn, it provided the basis for the operations of the more than 330 federally recognized tribes, on reservations or not, and the more than 220 federally recognized Alaskan Native Villages.

The larger American society's vision of American Indians as citizens was also manifest in its system of Indian education. In the early days, America established schools to educate Indians. In fact, the American system of higher education which began in the seventeenth century – the 'Ivy League' schools, in particular – was in part to educate Native Americans, as reflected in the charters of, for example, Harvard University and Dartmouth College. With the development of the reservation system and the development of the system of elementary and secondary education in the United States, a natural alliance was born, and some treaties provided funds for reservation schools. By the beginning of the twentieth century, there were more than 200 government schools on reservations, supplemented by schools funded reluctantly funded by states for Indian youth, and some schools in soon-to-become Oklahoma, primarily under the auspices of the Five Tribes there. By the mid-1920s, however it became apparent that these schools – particularly the boarding ones, but also the day schools – were not effective as avenues to mainstream America: rather, they were a national disgrace. In 1928, the Meriam Report (Meriam, 1928: p. 348) stated that the "Indian problem is essentially an educational one," and called for a redirection of Indian education. Eventually, schools for American Indians became more sympathetic to Indian cultures, and began to incorporate Indian history and culture into the curriculum. Following World War II, however, boarding and day schools for Indians began to decline, and by the 1950s public school education for Indians became the norm.

Urbanization

Coinciding with the increase in the American Indian population beginning with the twentieth century, and with the dispossession of Indians from their lands, were the beginnings of a small but steady increase in the proportion of the population that lived in urban areas. Less than one-half of 1% of the American Indian population of the United States lived in urban areas in 1900; by 1950, more than 13% of the population lived in urban areas; at the time of writing, well over half of the American Indian population lives in urban areas, and the remainder live on reservations or in rural areas. (Only about half of the Native Americans in Canada live in cities, a substantial increase from about one-third in the 1970s, and a mere one-eighth in the early 1960s.) In part, this was a result of American Indian servicemen and women returning to cities rather than to small towns or rural areas following World War II. It was also a result of the mid-twentieth-century Bureau of Indian Affairs relocation program that encouraged and assisted American Indians to relocate to urban areas.

Native Americans Today

The Native American population in the United States and Canada experienced significant population recover during the twentieth century. From the nadir population of about 375 000 at the start of the twentieth century, it increased to more than 5 million self-defined Native Americans and mixed Native Americans in the 2010 US census plus more than 1 million self-defined 'Aboriginals' in Census Canada 2011. (See Shoemaker (1999), Ubelaker (1988), and Thornton (2000) for considerations of Native American population recovery.) This occurred because Native American mortality rates decreased, and fertility rates remained higher for Native Americans than for the total population. It also occurred because of changing census definitions of Native Americans in the United States, whereby individuals formerly classified as non-Native Americans became classified as Native Americans through self-identification in the censuses.

Tribal Membership

Most individuals self-identified in US censuses reported a tribal affiliation. The largest reported tribal affiliations include Cherokee, Navajo, Chippewa (Ojibwa), Sioux, Choctaw, Pueblo, Apache, Iroquois, Lumbee, and Creek. Not all of those in the Native American population are actual members of Native American tribes, however. Only about two-thirds of those self-identified as Native American in the recent US

decennial censuses are actual members of one of the federally recognized tribes or Alaskan Native Villages.

In Canada, the situation is different. There one must be registered under the Indian Act of Canada to be an 'official' Indian. Categories of Indians there include either status (or more or less 'registered') Indians – those recognized under the Act – and nonstatus (or more or less 'nonregistered') Indians – those who never were registered or gave up their registration (and became 'enfranchised'). Status Indians, in turn, are subdivided into treaty and nontreaty Indians. Canada also has the *Metis*, individuals of Indian and white ancestry who are recognized as such but not legally recognized as Indians. (This group is not generally 'land based' although there are several land-based *Metis* communities in Alberta.) Most Canadian Indians are registered, however.

Distribution

Only about one-quarter of Native Americans in the United States live on the more than 300 reservations and trust lands in the United States. About half of these live on the 10 largest reservations (and trust lands): Navajo Reservation (and trust lands); Pine Ridge Reservation (and trust lands); Gila River Reservation; Papago Reservation; Rosebud Reservation (and trust lands); San Carlos Reservation; Zuni Pueblo; Hopi Pueblo (and trust lands); and Blackfeet Reservation. Conversely, about two-thirds of the registered Indians in Canada live on more than 600 reserves there.

According to census data, the states with the largest Native American population include California, Oklahoma, Arizona, New Mexico, Alaska, Washington, North Carolina, Texas, New York, and Michigan. United States cities with the largest Native American populations include New York City, Oklahoma City, Phoenix, Tulsa, Los Angeles, Minneapolis–St. Paul, Anchorage, and Albuquerque. Canadian provinces with the largest number of Native Americans are Ontario, British Columbia, Saskatchewan, and Manitoba. And, there is now in Canada a new Native American-controlled province of Nunavut.

Anthropology and the Study of American Indians

Europeans who colonized North Americans soon developed intellectual interests in the native peoples here. They had to explain where the natives came from, but they were also in awe of native customs and cultures. Early explorers even sent Native Americans back to Europe, so that Europeans could see them for themselves. Eventually, prominent European scholars such as Thomas Malthus and G.W.F. Hegel developed an interest in these people and sought to integrate them into their study of human history, although Malthus considered Native Americans as 'wretched,' and Hegel thought they lacked history and would disappear.

In the late nineteenth century, however, Lewis Henry Morgan wrote of the native peoples of North America, including his two classics, *League of the Ho-de-no-sau-nee*, or *Iroquois* (1851) and *Ancient Society* (1877). He argued that they were disappearing and called for their study – documentation – before this happened. Others, such as Emile Durkheim, Sigmund Freud, Karl Marx, and Frederick Engels, also drew upon Native American societies and cultures in their writings. Although the interest here was decidedly on social evolution – with Native Americans being at the lower stages – intellectual interests changed in the early twentieth century toward how individual elements in societies and cultures were integrated to form a whole. Anthropology in the United States was now separating itself from sociology and coming into its own, with a decided interest in the native peoples there. In California, for example, Kroeber heeded Morgan's earlier call and sought in the first decades of the twentieth century to describe California Indians before they disappeared, or changed their ways of life fundamentally. In this regard, the well-known Ishi – the so-called last wild Indian – became a person of curiosity for Kroeber and others. Anthropology and history soon rejoined forces at mid-century, however, with the decided interest in studying Native Americans using the newly developed idea of 'ethnohistory.'

It was not too long before Native Americans became more involved in setting research agendas about themselves, and reacted against the study of them by anthropologists. Many rallied around Vine Deloria Jr.'s critique of anthropology in his *Custer Died for Your Sins* (1969), and his depiction of anthropologists as 'anthros.' Coinciding with this was the emergence of Native American studies in colleges and universities in the United States, and Native studies in Canadian counterparts, as a reaction toward both anthropology and the neglect of the study of Native Americans in other disciplines (Thornton, 1998a).

At the time of writing, anthropology, Native American studies, and Native Americans have achieved a truce, although an occasionally delicate one, in no small part because anthropologists have gained a new respect for Native Americans. Coinciding with an increased degree of self-determination of Native Americans in American society was the passage of the National Museum of the American Indian Act in 1989, both creating a national museum at the Smithsonian Institution devoted to Native Americans, and mandating the return of Native American human remains and funerary objects held at the Smithsonian, primarily in the National Museum of Natural History. A year later, the Native American Graves Protection and Repatriation Act was passed which mandated the repatriation not only of human remains and funerary objects from all institutions receiving federal funding but also the return of Native American objects of cultural patrimony and sacred objects. The Smithsonian, already required to repatriate human remains and funerary objects, was exempt from this legislation. However, the National Museum of the American Indian Act was amended in 1996 to include the required return of objects of cultural patrimony and sacred objects held at the Smithsonian.

Smithsonian repatriation is monitored by a seven member committee mandated by congress, and it is required that the majority of its members be selected from nominations submitted by Native American tribes. From its inception in 1990 to the early 2000s, it was chaired by Russell Thornton. To date, several 1000 sets of human remains and numerous cultural objects have been returned to Indian tribes from the Smithsonian. Included here are human remains from the Sand Creek and Fort Robinson Massacres, Ghost Dance shirts and other objects from the Wounded Knee Massacre, and Ishi's

brain, and Sitting Bull's braid, cut from their bodies at their autopsies and sent to the Smithsonian.

These national repatriation laws and state laws as well, have in turn forged new relationships between museums, archaeologists, physical anthropologists and ethnographers, and Native Americans (Thornton, 1998b).

The study of Native Americans, by both non-Native and Native scholars, in anthropology and other disciplines, will continue; however, Native Americans will have an increasing role in determining what, how, and by whom it is studied.

Abstract

The modern Caribbean emerged through the transformations that took place with European colonization, which resulted in the establishment of large-scale plantation societies and the repopulation of the area with Europeans, Africans, and Asians. This resulted in societies that are stratified in terms of race and class, culturally diverse and highly mobile. Key issues in research on sociocultural aspects of the area include African continuities, the cohesion of societies, the coexistence of contradictory value systems linked to colonial and local frameworks of life and their (re)interpretation in everyday life, the role of out-migration, and the development of transnational sociocultural systems.

A Geographical Entity

Viewed as a geographical entity the Caribbean consists of a long chain of islands, enclosing the Caribbean Sea and separating it from the Atlantic Ocean, as well as a smaller number of islands located within the Caribbean Sea. Comprising almost 1000 named islands and islets and extending across 2500 miles, the archipelago runs from Florida in a southeasterly direction toward Trinidad where it then continues in a westward direction along the northern part of the South American coast.

Four groups of islands can be distinguished. The Bahamas, consisting of approximately 700 islands, 30 of which are inhabited, is the northern-most group. Further south are the Greater Antilles, home for the vast majority of the area's about 40 million inhabitants and comprising Cuba, Hispaniola (divided into Haiti and the Dominican Republic), Jamaica, Puerto Rico, as well as a number of smaller islands that are associated with them. From the southeastern end of the Greater Antilles and stretching in a north-south direction to Trinidad is a long chain of islands known as the Lesser Antilles. About 40 of these islands are inhabited, and they are divided into the Leeward Islands (in the north) and the Windward Islands (in the south). Finally, a smaller number of islands located along the South American coast, and sometimes referred to as the Leeward Antilles, comprise the fourth group of islands.

The Caribbean is usually also seen to include Guyana, Suriname, and Cayenne (French Guiana) on the South American coast, Belize on the Central American coast, and the Colombian islands off the Nicaraguan coast, due to their shared colonial history with the Caribbean islands. Bermuda, further north in the Atlantic Ocean, is also sometimes regarded as part of the Caribbean because its population is mainly of Caribbean origin. Furthermore, in recent decades large Caribbean communities have developed in various North American and European metropoles, as substantial segments of the Caribbean population have relocated abroad. It is therefore difficult to make a clear-cut delineation of the Caribbean as a geographical region when viewing it from a historical and sociocultural point of view.

A Historical Perspective

Today the Caribbean is probably best known as a major tourist destination, visited every year by millions of North American and European visitors, who are attracted by the white sandy beaches and tropical climate, often moderated by pleasant trade winds. From the late fifteenth to the late nineteenth centuries, however, the area played a key role in European colonial ventures. It attained prominence in modern colonial history because it was easily accessible to the early seaborne colonization of the 'new world,' and a large number of European states have operated in the area, including Spain, Britain, France, the Netherlands, Denmark, and Sweden. After Columbus discovered the Caribbean islands (and thus the Americas) in 1492, the area became known for its pirates and buccaneers. In the course of the seventeenth century, however, it developed into a center of large-scale sugar production for export using a slave labor force imported from Africa, thus setting in motion the trans-Atlantic triangular trade.

The modern Caribbean, as we know it today, emerged through the complete transformation that took place with this European colonization. The Indian (or Amerindian) people living by agriculture and fishing in the area virtually disappeared within 50 years of Columbus's discovery, as they succumbed to new diseases brought by the colonizers, as well as the colonizers' violent forms of subjugation. They were first replaced by indentured European workers and then enslaved Africans brought to the Caribbean through enforced transportation, as the European colonizers needed a massive supply of laborers to run the plantations producing sugar for the world market. When the trans-Atlantic slave trade was stopped in the nineteenth century, an estimated 3 million Africans had been transported to the Caribbean. With the abolishment of slavery, initiated in the 1830s in the British colonies, many of the freed slaves left the sugar estates and established peasant villages of their own. Others migrated for economic opportunities in urban areas or in other Caribbean societies. This led to the recruitment of approximately a half million contract laborers in Asia, most of them deriving from India.

From the end of the nineteenth century, the European colonies experienced economic decline, as plantation production became less profitable. The European plantocracy, however, maintained economic control, making it difficult for the Caribbean population to develop a viable, alternative economic system. At the same time, the colonial regimes instituted a number of 'civilizing' efforts focusing on missionizing and educational activities intended to create loyal

colonial subjects. Nevertheless, out-migration continued and the post-emancipation period saw the establishment of a strong, still vibrant migration tradition involving population movements to areas of greater social and economic opportunity. During the nineteenth and first half of the twentieth century, migration primarily took place within the Caribbean area. Since the 1950s, however, it has been directed especially toward Europe and North America.

Politically, Haiti was the first Caribbean society to achieve independence – in 1804 after a slave uprising. It was followed by the Dominican Republic in 1821 and by Cuba in 1902. The rest of the Caribbean became decolonized in the post-World War II period, with most of the British possessions gaining independence and most of the Dutch and the American areas attaining partial independence, though Suriname gained full independence. The French colonies, on the other hand, were incorporated as overseas departments into France. Local political systems have ranged from dictatorships to parliamentarian systems based on free elections (Trouillot, 2001).

As can be seen from this history, from a sociocultural perspective the Caribbean may be characterized as an assortment of territories linked to the Caribbean Sea sharing a past of early European colonization that led to the extinction (or displacement) of the indigenous population, the establishment of exploitative European colonies, and the massive importation of an enslaved or contracted labor force from Africa and Asia. Out of this colonial past emerged a range of societies that can be described as highly stratified, culturally heterogeneous, and extremely mobile.

Anthropological Beginnings

The anthropological discipline evolved out of a concern to document and analyze indigenous sociocultural entities, whether through ethnographic fieldwork in local communities in Africa or Oceania, or by doing salvage ethnography among survivors of North American tribal societies on the verge of extinction. Anthropology therefore has not been well equipped to deal with a sociocultural area in which the original population has been largely eradicated and the new populations have been highly complex and mobile. Having virtually no indigenous population, the Caribbean, in fact, generated little interest in anthropology before the middle of the twentieth century. One of the few anthropologists to do substantial research in the area was Melville Herskovits who conducted fieldwork in Suriname, Haiti, and Trinidad during the 1920s and 1930s. His goal was to examine how the culture of the descendants of the African slaves could be seen to be based on retentions and reinterpretations of the culture of their African ancestors who were forcibly transported to the New World as slaves. In this endeavor he sought to counter racist charges that the blacks in the New World had no distinct culture of their own; however, his methodological approach – looking for cultural links through a comparative framework establishing the extent to which Caribbean cultural traits had retained their Africanness – has been criticized as crude and lacking an understanding of historical processes. Nevertheless, Herskovits is still known for his central role in establishing the 'New World Negro' as a legitimate area of study (Scott, 1991). Early anthropological research thus was grounded in an interest in the impact of the African past on not only Caribbean but black culture more generally.

Caribbean culture and society became the subject of sustained ethnographic research only after World War II when social and economic change became a topic of interest in the discipline. This reorientation of anthropology has been linked to two different political developments that generated an awareness of the possibility of broadening the scope of anthropological research. It led, however, to rather different theoretical approaches.

One development pertains to concern about the Cold War. According to David Scott (2004: 195) this led, in the United States, to a "new alliance between the intelligence apparatuses of the US state […], the philanthropic foundations [… and] key universities" that "reimagined the globe as a number of strategic research 'areas,' and enabled, underwrote, and shaped the new area-studies-directed social science of the post-war era." A concrete result of this alliance, and the research it enabled, was a major collaborative research project, directed by Julian Steward, that led to the publication of *The People of Puerto Rico* (Steward, 1956). This edited volume examined the development of Puerto Rican society, its varying subcultures associated with different material conditions of life and the ways in which they were integrated into the larger national community.

One of the participants in the project was Sidney W. Mintz, who did research in the southern part of Puerto Rico dominated by large-scale production of sugar cane. Like his American predecessor Melville Herskovits, Mintz, who became one of the leading figures in the anthropology of the Caribbean, was interested in the historical formation of Caribbean culture, but unlike Herskovits he did not look primarily for African continuities. Rather he investigated the culture building that took place within the Caribbean as people created a new life for themselves there, drawing on the range of material, social, and cultural resources available to them (Mintz, 1974; see also Mintz and Price, 1992). In a number of studies, Mintz documented how African-Caribbean communities emerged during slavery in the margins of the plantation systems representing a mode of 'accommodation' and, at the same time, 'resistance' to slavery and the dominant plantation society with which it was associated. These communities, he showed, became an important foundation for the peasant villages that were established after the abolishment of slavery (Mintz, 1974).

Throughout his studies Mintz emphasized that the Caribbean societies were essentially modern, having emerged within the 'agro-industrial enterprises' of the large-scale plantation system that he described as "landmark experiments in modernity" (1996: 295–297). According to Mintz, this modernity, which entailed the recruitment of labor power from different places, required that people had a 'non-valuative' openness toward cultural difference, partly because there was no 'institutional recourse to a standard common tradition.' While the Caribbean societies might display strong socioeconomic similarities, linked to their common colonial past, they were thus, according to Mintz, culturally heterogeneous and therefore not a 'culture area' in the sense of sharing particular cultural institutions and associated values.

The other political development that contributed to the establishment of the anthropological study of the Caribbean had to do with the need to address the social and economic problems that plagued the late colonial societies. In social science this led to an interest in societal integration both at the micro level of the family and the household as well as sociocultural integration at the wider societal level, as the British colonies moved toward political independence (Slocum and Thomas, 2003: 555). The work on micro-level integration, states Michel-Rolph Trouillot, was spurred by a "concern for policy on the part of officials who saw Afro-Caribbean families as 'deviant' simply because they did not fit the nuclear folk-model of Western consciousness" (1992: 26). Thus, even though some of the anthropological studies, published beginning in the 1950s, produced fine ethnographies of local communities (see, for example, Smith, 1956; Clarke, 1957), their analyses became entangled with colonial, bureaucratic understandings of Caribbean family forms as dysfunctional and as an important cause of the poverty of the African-Caribbean population. As noted by Trouillot (1992: 26), Raymond T. Smith's term matrifocal family, meant to point to the central role of women as mothers, came to signify female-headed (or perhaps rather, father-absent) families, whereas Edith Clarke's monograph *My Mother Who Fathered Me* (1957), which documented important aspects of rural communities in Jamaica, including the key role of family land (a kin-based form of shared land holding), became perceived as a study in social pathology.

Family studies became part of the larger discourse on the nature of Caribbean societies, where R.T. Smith and Michael G. Smith were the major protagonists. R.T. Smith contended that West Indian societies were integrated in terms of sharing cultural values and social norms but, at the same time, stratified due to the existence of color and class hierarchies that influenced the ways in which these values and norms were implemented in practice. He thus argued that all layers of Caribbean societies shared an ideal of the nuclear family, based on marriage, but that this ideal tended to be realized as a family form only in certain phases of the life cycle of individuals and the domestic units to which they belonged (Smith, 1956). M.G. Smith, however, maintained that West Indian societies were characterized by cultural pluralism, a concept he had adapted from John S. Furnivall's plural society theory developed in relation to South-East Asian colonial societies. According to M.G. Smith, Caribbean societies thus consist of groups that adhere to disparate social institutions and cultural norms, so they are only kept together through the power of the dominant segment of the society. He therefore maintained, and sought to demonstrate through statistical analysis as well as detailed ethnography, that West Indians do not share a common family ideal but operate according to different sets of cultural values and social norms (Smith, 1962a, b).

During the 1960s, the anthropology of the Caribbean was dominated by the debate between the cultural integrationalist and the cultural pluralist approaches. This debate, Karla Slocum and Deborah Thomas (2003: 555) state, was nourished by the "then-dominant social science view [which] held that social systems needed to be integrated around a common value system in order to thrive without an overarching (external) system of power and control." It was not before this view was superseded by a more dynamic, practice-oriented notion of sociocultural systems that the anthropology of the Caribbean moved beyond this theoretical and analytical impasse.

Caribbean Culture as Negotiated

The ethnographic studies of Peter Wilson (1969, 1973), based on fieldwork on the island of Providencia, played a key role in the development of new approaches that could move beyond the integrationalist-pluralist divide. Wilson proposed that Caribbean societies be conceptualized as shaped by dual cultural value sets centering on the opposing notions of respectability and reputation. According to Wilson, the value set of respectability emphasizes marriage and the nuclear family, sexual restraint, godliness and education, and was primarily linked to the colonial society, the middle class, and to women whose lives tended to center on the domestic unit and the church. Reputation, on the other hand, celebrates sexuality, the begetting of children, and sociability in public arenas such as the rum shop or the street corner – informal arenas of social life in the local communities where men tend to be more active. While Wilson linked the value sets to different social contexts, he did not see Caribbean societies as divided into disparate and separate modes of life. On the contrary, he emphasized that the two, opposing value sets were continuously played out against each other in social life as individuals drew on various aspects of the two, depending on the particular situation in which they found themselves. By seeing the two value sets as different, yet part of the same social system, Wilson thus combined an integrationalist and a cultural pluralist understanding of Caribbean culture.

Wilson's conceptual scheme has been highly influential in stimulating a more practice-oriented approach that can capture how individuals negotiate different, even conflictual, values and norms, as they seek to position themselves in society. It has also stimulated important critiques and suggestions for further theoretical refinement. Diane Austin-Broos (Austin, 1983), among others, has pointed out that Wilson's scheme needs to incorporate the issue of power – not just in terms of political and economic domination, but also in the sense of ability to "constrain ideas and to intervene in attempts to construct alternative models of society" (1983: 223). She therefore calls for a distinction between culture and ideology: "divergent cultures can persist within larger ideological schemata and do not necessarily signal the end of domination" (1983: 225). She proposes that Caribbean societies represent *a situation of conflict contained by domination* and that this should be a key topic in the anthropology of the Caribbean (1983: 223).

Wilson's scheme has been subject to the most criticism among anthropologists concerned with gender roles in the Caribbean. One of them is Carla Freeman who has argued that there are "competing and co-existing models of femininity that encompass not only those attributes and qualities of 'respectability' [mentioned by Wilson] but also elements that he would have located under the masculine heading of 'reputation' " (Freeman, 2002: 76). She further suggests that 'respectability' is a more dynamic value set than Wilson

acknowledges, because it may be renegotiated and find new forms of expression as Caribbean societies change through time. In her own work she has demonstrated this through an analysis of the ways in which women employed in the informatics industry in Barbados use this institutional structure as a framework within which to express their identity as women using clothing as a way of displaying their respectability (Freeman, 2000).

In yet other studies anthropologists have sought to improve Wilson's scheme by redefining the notions of respectability and reputation. In his work on consumption in Trinidad, Daniel Miller (1994) has thus suggested that Wilson's scheme can usefully be reconceptualized in terms of the notions of transcendence and transcience. Whereas the former, according to Miller, is linked to the internal, domestic sphere and validates the significance of enduring relations and values associated with the family, the latter is associated with the external, public sphere and the shifting relations, practices, and norms associated with modernity. In yet another attempt to further develop Wilson's conceptual framework, Huon Wardle has argued that its somewhat rigid duality can be broken down by rethinking the opposite pair of respectability and reputation in terms of 'commitment' and 'disjuncture,' notions that he sees as "less restrictively laden terms for the polarity of cultural accommodation and cultural confrontation that Wilson emphasizes as crucial" (Wardle, 2007: 569). Furthermore, he proposes adding a third dimension to this dualistic opposition: 'ambiguation' – a 'principle of mediation' that enables individuals to negotiate the social gap created by the radical differences between the disparate notions.

Creolization

Another strand of research, examining the complexity of Caribbean culture and society, has taken its point of departure in creolization processes, borrowing a concept of linguistics. In a study of Guyana, Leo Drummond shows that culture can be understood in terms of a continuum of cultural variation, expressed in a Guyanese context in terms of ethnic categories such as 'English' or 'white,' 'bush' (indigenous Indian), 'coolie' (Asian Indian) that are attributed with varying meaning, as individuals interact (1980: 357). Individuals will learn to master the smaller segment of the continuum where they are positioned, but even in these contexts they will encounter divisiveness and conflictual rules that they must negotiate in social practice (1980: 368). A creole model of culture, according to Drummond, leads to a new concept of culture, because a continuum will have no clear societal boundaries and be under constant transformation, as the meaning of cultural categories and customs are constantly defined and redefined in social life.

From a rather different perspective, Jean Besson has examined creolization through time, inspired by Sidney Mintz's historical approach. She conceptualizes creolization as a complex process involving "subaltern opposition and resistance to hegemonic power reflected in class conflict" as well as "adaptation and negotiation across class boundaries" (e.g., Besson, 2011: 29). She argues that creolization at its core concerns practices of 'localization' or 'indigenization' engaged in by the descendants of those who came from Europe, Africa, and Asia. Furthermore, she sees these practices as involving an ongoing quest for belonging within societies dominated by capitalist class relations linked to a global economy and changing colonial and postcolonial regimes (2011: 28). In several studies of Jamaican communities, she thus shows how kinship, land, and religion may be attributed with novel meaning and find expression in new practices, as people respond to changing conditions of life through time.

Some students of Caribbean culture, however, have been rather skeptical of the notion of creolization. Stephan Palmié, for example, maintains that its focus on the mixing of cultures entails a culturally essentialist understanding of the existence of different cultural entities that can be blended. He therefore suggests that theory of creolization should be "an object of, rather than a tool for, anthropological inquiry" (2006: 448). Such an inquiry can be found in Aisha Khan's (2004) ethnographic analysis of Trinidad. She argues that ideologies of mixing are prevalent in the Caribbean and Latin America and should be viewed as "causal forces in social processes." Thus, they often define certain population groups, such as the Indians or the Chinese, as non-Caribbean because they are not viewed as part of the black-white mix seen to constitute the backbone of Caribbean society.

The analysis of the concept of creolization makes an important, more general, point by highlighting the close connection between social science concepts and societal, normative notions. This issue is of particular salience in research on Caribbean culture and society that has developed within a hierarchical colonial context where it was not possible to establish 'traditional' frameworks of cultural particularistic interpretation associated with indigenous groups. The critique of the metaphor of mixing that has been associated with creolization, however, does not invalidate the importance of investigating Caribbean sociocultural processes through time in relation to changing global structures of inequality, as Besson has done in her work.

Mobility and Transnational Relations

During the last decades, anthropological studies of the Caribbean have increasingly moved out of the Caribbean as a geographical entity in acknowledgment of the massive outmigration from the area, which, as noted, has led to the emergence of large populations of Caribbean origin in North America and Europe. With this research has come the recognition that the Caribbean as a sociocultural area is deeply embedded in extensive fields of relations extending to migrant destinations in different parts of the world. One of the first to point to the significance of such fields was Stuart Philpott (1968), who, inspired by the Manchester School's studies of urban Africa, focused on the social networks connecting Caribbean sending societies and migrants abroad. By following the migrants from their Caribbean island of origin to London (thus demonstrating the value of doing multi-sited ethnographic fieldwork 30 years before it became fashionable in anthropology), he documented the emergence of a translocal community based largely on expectations and

obligations rooted in family and kinship that shaped, and were shaped by, life in the Caribbean as well as in London.

Following Philpott's work, a large number of studies (see Slocum and Thomas, 2003) have documented the key role of migration in Caribbean culture and society. They have shown that most people do not view migration as a means of leaving home with the intent to settle in another place, but rather as a resource that makes it possible for them to explore various opportunities abroad and enjoy social mobility, while remaining part of their Caribbean home community of origin. They therefore generally migrate with the intent to return, and many send considerable remittances to relatives in their community of origin, visit as often as possible, and even invest in homes of their own in the Caribbean.

This research has demonstrated that migration is an integral aspect of Caribbean societies. Thus, the great variability of domestic units to be found in the Caribbean should be seen within the context of the extensive networks of relations that link migrants engaged in wage employment abroad with their parents, siblings, and children in the family home in the local community. While some migrants do not succeed at supporting this family – including their own children left behind – many do and continue to be regarded as key members of the family home even if they live and work in distant destinations. This close relationship between migration and family relations has led Karen Fog Olwig (2007) to suggest that migration – despite the often prolonged physical absence that it involves – is an important way of doing family relations within the context of global systems of social and economic inequality. Thus trans-local family relations constitute not only key resources of economic support and social status for relatives left behind but also vital sources of identification and belonging for many migrants who may experience marginalization as ethnic minorities in the receiving societies. Family land can be seen to proffer a similar symbolic resource of import to migrants. As a form of land holding that allows the descendants of the original owner of the property to share land in common, it thus offers an (in principle) inalienable place of belonging in the Caribbean for migrants and their descendants (Besson, 2011).

This does not mean that it is unproblematic for Caribbean societies to be so strongly oriented toward migration. From a local point of view, the institution of family land, for example, can be viewed as a problematic form of land ownership that makes it difficult to earn a living on the land and therefore leads to underuse of local resources. Furthermore, the maintaining of close family relations over great physical distances may be fraught with tensions, disappointments, and personal sacrifice. This may become particularly apparent when migrants return to claim their place of belonging in the Caribbean (see, for example, Olwig, 2007).

If this migration research has shed interesting new light on Caribbean societies, its greatest impact seems to have been the challenge it has posed to notions of immigration and integration in the receiving societies in the Global North. In the United States, for example, immigration has played a major role in the development of the country, and there has been a strong tradition of investigating population movements to the country and the processes of assimilation into American society immigrants are assumed to undergo. As research on Caribbean migrants in the United States has demonstrated the key significance of continued ties to the place of origin, it has been necessary to reconsider the notion of migration as entailing a one-way move followed by processes of assimilation. In several studies, Glick Schiller and associates (Glick Schiller et al., 1992; Basch et al., 1994; Glick Schiller and Fouron, 2001) have argued, for example, that a key motivation for maintaining ties to the Caribbean is the rejection of the position as racialized others that Caribbean immigrants tend to be given in the bottom of the American ethnic hierarchy. Thus, many migrants not only actively sustain family relations across national borders but become involved in transnational sociocultural systems linked to ethnic organizations that can act as pressure groups in the receiving as well as the sending society. This has led many scholars to reconceptualize migrants as diasporas, population groups that remain oriented toward a distant homeland.

While this strong focus on the migration tradition in the Caribbean and the transnational communities, diasporic groups and ethnic mobilization with which it is associated has generated important new insights, it may be relevant to ask – inspired by the critique of the notion of creolization – whether it may end up defining Caribbean people as belonging to a liminal space outside the normal order of things.

This article is a revision of the previous edition article by M. Moscovitch, volume 1, pp. 1–10, © 2004, Elsevier Ltd.

Abstract

Amnesia refers specifically to the focal disruption of anterograde and retrograde memory, with no other major impairments or clinical features. The study of focal lesion patients has greatly advanced our conceptualization of memory systems and their neuroanatomical basis. Although these distinctions are still very relevant, recent research is challenging such distinctions, and the independence of memory systems that they imply. The authors review the major memory systems with relevant patient findings, and subsequently discuss new insights into how different types of memory are affected in amnesia. The authors finish with a discussion on the implications of recent research for theories of amnesia.

Memory loss is among the most widely studied cognitive disorders that occur following neurological insult. The classical amnesic syndrome is defined by a severe deficit in encoding new information (anterograde amnesia; AA) and by severely impaired recall of experiences that occurred some period of time before the trauma (retrograde amnesia; RA), with other cognitive abilities remaining relatively intact. Thus, following recovery from brain damage, if a patient with amnesia is presented with new information, he or she can keep a limited amount in mind if it is actively rehearsed, but that information will not be retained beyond the immediate moment once the patient is distracted. Moreover, if asked about a past event such as a recent holiday or a particular birthday, the patient may only produce a few general details, which are typically factual in nature and devoid of the rich detail associated with vividly recalling a past episode. Yet, when asked about previously learned knowledge, such as types of animals or historical events, patients with amnesia are not as impaired. Aside from these marked impairments in AA and RA, the amnesic patient has no major deficits in general intelligence, simple attention, language comprehension or production, visual perception, problem solving, planning, or regulating behavior. Thus, the description of the classical amnesic syndrome is one of a selective impairment in memory.

Memory loss is a common sequela following damage to a variety of structures, including the medial temporal lobes (MTLs), subcortical structures, frontal lobes, and even the parietal lobes (for a review of memory loss due to damage in other neural substrates, see Berryhill, 2012; Fama et al., 2012; Moscovitch and Winocur, 2002). This article focuses on the classical amnesic syndrome due to damage in the hippocampus, a deep structure in the MTL. In terms of anatomy, major pathways from the hippocampus project via the fornix to the mammillary bodies, anterior and dorsomedial thalamic nuclei, and eventually the prefrontal cortex. Some projections from the medial thalamic nuclei project back to the hippocampus via the cingulum, thus completing the limbic circuit (Brown and Aggleton, 2001). There are also reciprocal connections between the hippocampus and entorhinal cortex, and between left and right hippocampi.

The hippocampus is particularly susceptible to various types of neurological insults. Viral infections (Cermak and O'Connor, 1983), oxygen deprivation (i.e., hypoxia; Di Paola et al., 2008), epilepsy (Lehéricy et al., 1997), traumatic brain injury (McKee et al., 2009), electroconvulsive shock (Nakamura et al., 2013), and cerebrovascular accidents (i.e., strokes) can affect hippocampal tissue (Lim and Alexander, 2009). Amnesia can also result from damage to any regions in the limbic circuit: For example, diencephalic atrophy is a common consequence of Korsakoff's syndrome, which presents with AA, RA, and concomitant personality and cognitive features (Fama et al., 2012). Moreover, lesions to the fornix or thalamus are also sufficient to produce amnesia (Carlesimo et al., 2011).

In their seminal paper, Scoville and Milner (1957) reported on patient H.M., who required surgical resection of the MTL bilaterally to treat intractable seizures. H.M's profound memory deficits for new information, and subsequent studies of human patients and nonhuman primates, have shown that the hippocampus is necessary for encoding new information in order to be remembered subsequently (Alvarez and Squire, 1994; Gaffan and Murray, 1992). This is due to the anatomical position of the hippocampus, which receives input from various cortical regions via the entorhinal cortex, and thus is ideally situated to bind new information together into a multimodal representation (Squire, 1992).

Anterograde Memory Distinctions

Short-Term Memory and Long-Term Memory

Since the initial study on H.M., several key distinctions have been made in terms of different types of memory. In terms of the anterograde aspects of amnesia, one of the earliest distinctions was between short-term memory (STM) or primary memory for information held in mind shortly after presentation, and long-term memory (LTM), or secondary memory for information no longer held in mind but is retained over longer periods of time. Early studies showed that amnesics were generally comparable to healthy controls in terms of the amount of information they could keep in mind. However, once information was displaced with new stimuli, or after a given period of time had passed in which rehearsal was prevented, amnesics showed a discontinuous drop in memory performance. For example, both H.M. and healthy controls

could accurately recall a string of about six digits immediately after hearing them. However, with sufficient practice, healthy controls could recall an increasingly large number of digits (i.e., up to 20), whereas H.M. could not increase the number of digits he could recall beyond seven, despite dozens of repetitions (Drachman and Arbit, 1966). In addition, the ability to actively maintain and manipulate information in mind (i.e., working memory; WM), was generally found to be intact in amnesia (Baddeley, 2012; Cowan, 2001). For example, when shown a simple pattern of black and white squares and asked to recall it after 0, 4, 8, or 12 s, amnesics performed normally compared to healthy controls over short delays (Owen et al., 1995). Conversely, patients with lesions in the lateral temporal or parietal cortices showed deficits in STM but not in LTM: this demonstration of a double dissociation between lateral temporal and medial temporal regions for STM and LTM, respectively, suggests that these two aspects of memory are indeed separate, and that only the latter type required the hippocampus.

Memory above or below Conscious Awareness: Implicit and Explicit Memory

Another distinction was demonstrated between what is termed 'explicit' or 'declarative' memory and 'implicit' or 'non-declarative' memory. The former refers to any memory we are consciously aware of having, be it knowing the capital of France, or recalling a past summer barbeque. Implicit memory, conversely, refers to stored information that is retained or successfully retrieved without conscious awareness: crucially, although this information is retained subconsciously, it can nonetheless influence behavior. In general, despite their impairments in explicit memory, amnesics were largely intact on measures of implicit memory, such as learning a new skill. For example, amnesic people can learn a novel skill such as reading inverted text at a comparable rate to controls (Cohen and Squire, 1980; Moscovitch et al., 1986). Moreover, both amnesic people and controls show good retention of both the general skill and of particular exemplars, in that they can read them more efficiently when tested at a later time. However, although patients can read a list of inverted words more quickly and accurately, their explicit memory for those words will be poor following a delay, demonstrating their intact implicit memory for the skill of reading inverted text in general and specific exemplars in particular, but impaired explicit memory for what they read.

Amnesic people also respond more accurately or quickly to stimuli they had experienced before, but cannot recognize subsequently. An example is priming, where an individual responds more quickly to a previously presented word or concept, even if the presentation was very brief, and thus not consciously perceived. In the word-stem completion task, participants are shown a series of words e.g., HORSE, then subsequently shown a series of word stems e.g., HO____, and are asked to complete the word with the first one that comes to mind, as quickly as possible. Amnesic people are just as likely as healthy controls to fill in the stem HO____ with HORSE, rather than another word, such as HOUSE, even though they have no memory of seeing a list of words. Overall, these findings suggested that newly encountered information can be retained and recalled not only explicitly, as in recalling a past event memory, but also implicitly, such that one can have an enduring trace of memory that influences behavior subconsciously. The studies of priming and skill acquisition in amnesia showed that only explicit memory was impaired following hippocampal damage, whereas implicit memory, even for new associations, was spared (Goshen-Gottstein et al., 2000).

Retrograde Memory Distinctions

Semantic Facts and Episodic Experiences

Although it became clear that amnesia was characterized by AA for learning new explicit memory, patients also showed memory deficits for information acquired prior to their brain damage (i.e., RA). Here, too, there were perplexing inconsistencies. Specifically, variable evidence existed regarding (1) the types of explicit memories and (2) the age of the memories affected.

With regard to the former, it is important to distinguish between the amnesia for semantic and episodic memory (Tulving, 1972). Semantic memories are those pertaining to general knowledge, and are recalled as noncontextual facts without memory for a corresponding situation. Thus, when shown the word 'apple,' one can recall that an apple is a fruit with several varieties, but cannot typically recall when such facts were learned. In contrast, episodic memories contain information pertaining to specific life experiences, such as seeing the word 'apple' and recollecting the last time you had apple pie. Crucially, because episodic memories pertain to experiences, their recollection has the quality of autonoetic consciousness, or a feeling of reexperiencing the actual episode, whereas semantic memories have only noetic consciousness, or awareness only that the memory exists but no associated feeling of reexperiencing. Thus, amnesic people generally have poor episodic memory for autobiographical events spanning years to decades prior to their neurological insult. However, their memory for general knowledge, such as facts learned in school and well-learned information such family members' names, was less impaired. This impression was confirmed by early double dissociation studies showing that amnesic people were able to recall previously learned semantic facts for most of their life, except the more recent periods before their brain damage, extending for up to 10 years. Conversely, patients with damage to the anterior temporal lobes showed a loss of semantic memory, such as the names of objects in varying categories; however, their memory for past experiences remained relatively preserved (Hodges and Patterson, 2007). Similar patterns have been observed in Alzheimer's dementia patients, who have damage to the hippocampus early in the disease progression, and patients with semantic dementia, who have degradation of the anterior temporal lobes, and relative sparing of the hippocampi early in the disease. Alzheimer's patients show episodic memory loss and relatively intact semantic memory, whereas semantic dementia patients show relatively spared episodic memory and degraded semantic memory (Hodges and Patterson, 2007; Irish et al., 2011). Another example of the episodic-semantic distinction is in patients with

developmental amnesia, who sustain hippocampal damage shortly after birth. Although these patients typically have profound memory loss for their experiences, they can nonetheless acquire new facts, develop language skills, and progress in school at a level far above what would be expected based on the severity of their memory impairment (De Haan et al., 2006). Thus, such patients can go to class and acquire new information sufficient to complete a history test, but will have no memory of attending class or any classroom antics that may have occurred.

Autobiographical Recall of Recent and Remote Memories

Another contentious issue has been the extent to which amnesia will affect past memories. Specifically, there is a debate as to whether hippocampal lesions only affect recent memories (i.e., within the past few years) or both recent and remote memories (i.e., those stretching back to childhood). Early reports of patients with global amnesia caused by focal MTL lesions or Alzheimer's disease suggested that their RA follows a reverse gradient, with impoverished recent memories and largely intact remote memories (i.e., Ribot's law), suggesting that recent and remote memories were different in some way. These and other findings were consistent with a standard consolidation theory (SCT) of memory (Squire and Wixted, 2011), which states that the hippocampus helps initially to encode information into a lasting memory trace and to retrieve that memory. However, the hippocampus' influence will decrease over time as memory is eventually coded in the neocortex, during which time the memory can be retrieved without the hippocampus. Thus, recent memories are disproportionately affected in amnesia because they are still in the process of consolidation, which requires the hippocampus. Conversely, remote memories have been consolidated in the neocortex, and no longer require the hippocampus to be retained and retrieved. This would be the case for any explicit memory, be it episodic or semantic in nature. Evidence for SCT came from early work on RA (Moscovitch, 1982; Squire, 1992), and confirmed by later studies showing a severe loss of recent memories, with a varying extent of time period affected, but seemingly intact remote memories (Squire and Bayley, 2007). In addition, the generally poor ability for amnesics to encode new episodic or semantic information suggested that all memories first undergo a hippocampally dependent consolidation period (Squire and Wixted, 2011).

Recent evidence suggests, however, that although this model may apply reasonably well to semantic memory (but see Sharon et al., 2011), it fares less well with regard to episodic memory. Although people with amnesia may retain some memories for personal episodes, they are fewer and less rich and detailed than those of matched controls (Moscovitch et al., 2005; Moscovitch et al., 2006). The source of the discrepancy on the continuing contribution of the hippocampus to long-term retention, and retrieval of detailed autobiographical memories, is not known. The two leading candidates are differences in the site and extent of the lesions and the manner in which the memory was assessed, but neither has been successful in resolving all the discrepancies.

Updates on Current Memory Models: Exceptions and New Directions

Research on amnesia and the hippocampus has provided very useful distinctions as to the organization of memory, with the resultant models being a fruitful source of research. Although these distinctions generally hold, new theories based on recent findings in cognitive neuroscience have blurred the lines between different memory domains. In particular, earlier distinctions depended more on models based on memory stores, such as STM and LTM, their longevity (recent vs remote), and independent systems, such as implicit vs explicit memory. Once distinctions between implicit and explicit memory were questioned; however, it suggested that perhaps the preserved and impaired memory in amnesia was determined by the nature of memory representations. Similarly, as the distinction between STM and LTM began to be eroded by recent models describing the performance of neurologically intact people, so too did the functional dissociations in amnesia. Thus, several current lines of work suggest that the memory systems previously described may not be as independent of one another as had once been assumed, nor are they always easily dissociable in amnesia.

Is the Hippocampus Working during Working Memory?

Early theories of WM suggested information was held in temporary storage systems (i.e., 'buffers') separate from LTM, and acted upon by top-down control processes. Thus, retention of incoming information in WM existed separately from information in LTM, and would be subject to forgetting if not actively rehearsed or processed (Baddeley, 2012). However, other models eliminated the notion that WM buffers are separate from LTM. Instead, unitary-store models suggested WM is a limited capacity system that devotes attention to information represented in LTM. Thus, information in WM is merely activated LTM, rather than existing in a separate representational system. Crucially, the relative amount of information that may be kept in WM depends on factors such as the familiarity of incoming information, suggesting that more information can be kept in mind if it is based on preexisting LTM representations or knowledge (Cowan, 2001). If this is the case, it should be possible to find deficits in WM in amnesics under certain conditions (for reviews, see Jonides et al., 2008; Ranganath and Blumenfeld, 2005).

Indeed, Olson et al. (2006) had amnesic people and healthy controls remember three objects, three locations, or the three object–location combinations in a 3 × 3 array shown on a screen. Amnesic people showed no deficits when tested 1 s after the stimuli was presented, but could not recall object–location combinations after an 8-s delay. Similarly, Hannula et al. (2006) presented amnesic people with a continuous stream of relational information (i.e., face–scene pairings and location of items in a scene), and were probed for memory for the associations after one, five, or nine trials had elapsed. Although memory for face–scene pairs was intact after one intervening trial, amnesic people showed poor memory after as few as five trials.

These findings suggest that it may be inaccurate to characterize amnesia as an impairment of LTM only, and that under

certain conditions WM performance may also be impaired, particularly if the stimuli are novel or complex, such as a busy scene or a human face (Ezzyat and Olson, 2008; Hannula et al., 2006). Simple WM tests used in early studies of amnesic people often used digits or highly familiar words that are well learned, and thus their retention in WM may have been supported by extrahippocampal cortical structures responsible for their perceptual processing (Ranganath and Blumenfeld, 2005). Another interpretation is that WM tasks with sufficiently complex stimuli are more resource demanding, and thus require LTM as well as WM. Consequently, the amnesic deficit under these conditions reflects impaired LTM ability, rather than impaired WM per se (Jeneson and Squire, 2012; Warrington and Taylor, 1973). Regardless of the correct interpretation, it is increasingly clear that whether newly presented information is being stored temporarily in STM, or has been encoded into LTM is not as easy to discern as previously thought, and can be mediated by the nature of the memoranda (Ezzyat and Olson, 2008; Warrington and Taylor, 1973; see also Waugh and Norman, 1965).

Remembering Secretly: Hippocampal Implications during Implicit Memory

Another issue is whether the hippocampus is only involved in explicit memory, or whether it supports memory regardless of conscious awareness. Although early studies supported the independence of implicit and explicit memory, such findings of spared implicit memory were not always consistent, and depended on specific conditions for different tasks. Moreover, some suggested that priming effects were inflated in patient groups because of their lower baseline priming performance, as priming is always calculated as improved performance after exposure to stimuli, compared to no exposure (Ostergaard, 1994). Furthermore, subsequent analyses of priming showed that explicit memory sometimes contaminated performance on implicit memory tests in the healthy controls. For example, in Gooding et al. (1999), some subjects reported being aware that previously studied words were being tested in word-stem completion, with some even reporting purposely not using the previously studied words. These inconsistencies suggested that these tests did not always yield pure measures of implicit memory, weakening the notion that amnesic people have normal implicit memory.

Recent studies using more nuanced measurements have shown that hippocampal damage can indeed affect implicit memory. For example, Ryan et al. (2000) recorded participants' eye movements while viewing complex nature scenes. Critically, the researchers made very quick, subtle changes to the scenes that could not be consciously perceived. Controls made many new eye movements to the location of the scene change, whereas amnesics did not consistently show such behavior, suggesting they did not perceive the change because they did not have a coherent representation of the previous scene. Similarly, Hannula and Ranganath (2009) measured hippocampal activation and eye movements in healthy controls who previously viewed pairs of faces and scenes. During a later recognition test, subjects were shown the scene with several faces and asked to choose which face was previously shown with the scene. Subjects showed eye movements toward the location of the correctly paired face up to 1000 ms before explicitly recalling the correct face paired with that scene. Surprisingly, even on some trials when subjects incorrectly identified the proper face, they nonetheless made eye movements toward the correct face, and these eye movements were correlated with hippocampal activity during these trials.

Finally, there is evidence to suggest that implicit and explicit memory interact. Sheldon and Moscovitch (2010) had subjects study a set of words, and complete an implicit and explicit memory test with those words. In the implicit test, subjects viewed a series of rapidly presented words or nonwords and decided as quickly as possible whether the word was real or not (i.e., lexical decision). Subsequently, subjects were shown the study words with other new words and asked if they recognized seeing them before; if so, they were further asked whether they recalled an associated episodic detail with that word (i.e., recollection), or just knew they had seen it before but did not remember the experience of seeing the word (i.e., familiarity). Numerous studies using this recollection/familiarity distinction have shown the hippocampus is important for recollection, but not familiarity (Cohn et al., 2009; but see Kirwan et al., 2010). Curiously, words that were recollected were identified more quickly during the lexical decision task than familiar words, suggesting that hippocampally mediated processes may underlie performance on both explicit and implicit memory measures. Overall, these findings question whether conscious awareness is an absolute rule in determining which memory processes require the hippocampus (Dew and Cabeza, 2011; Hannula and Greene, 2012).

Experiences as Facts and Vice Versa: The Interdependence of Episodic Memory and Semantic Memory

Although there is wide agreement regarding the distinction between semantic and episodic information, these systems nonetheless are interdependent, which was evident even in the earliest theories delineating episodic memory and semantic memory (Tulving, 1972). Indeed, patients with hippocampal damage sustained in adulthood typically show very poor encoding of new semantic facts, often requiring many trials in order to retain new knowledge. Moreover, their ability to acquire new knowledge seems to correlate with MTL volume (Greenberg and Verfaellie, 2010), suggesting that at initial encoding both episodic memory and semantic memory are dependent on the hippocampus. However, by using mnemonic strategies such as errorless learning or fast mapping, amnesics can demonstrate better or even normal acquisition of new knowledge, although whether such information is retained over the long term is not always clear (McKenna and Gerhand, 2002; Sharon et al., 2011).

Even studies of healthy subjects report interactions between semantic memory and episodic memory. For example, newly encountered information that is congruent with previous knowledge is better recalled than incongruent information, demonstrating how semantic memory influences episodic memory (Craik and Tulving, 1975). More recently, amnesic people have also demonstrated this effect; when asked to remember grocery items with realistic or unrealistic prices,

amnesic people with damage limited to the MTLs showed the congruency effect, whereas those with lesions extending into lateral temporal cortices did not (Kan et al., 2009).

There is also evidence to suggest that episodic memory influences semantic memory at retrieval. For example, when shown faces and asked to identify whether they are famous or nonfamous, participants are quicker to identify a famous face if they have a specific episodic memory associated with that face, compared to faces they know are famous, but are not tied to any specific personal memory (Westmacott and Moscovitch, 2003). Finally, patient and functional magnetic resonance imaging (fMRI) studies both point to a role for the hippocampus during semantic retrieval tasks such as category fluency, where subjects are given a category and asked to think of as many exemplars from that category as possible (Greenberg et al., 2009; Sheldon and Moscovitch, 2012). Notably, some categories can be thought of as more episodic-like in nature, rather than strictly noncontextual facts. For example, thinking of items found in a kitchen may prompt one also to recall their own kitchen, which engages episodic memory, rather than searching through semantic memory only. Overall, it is clear that although semantic information can be accessed independently of the hippocampus, knowledge is inevitably intertwined with past experiences, and the two may complement one another at encoding or at retrieval.

Recent and Remote Memories: A Lasting Role for the Hippocampus?

Although initially a good description of RA, the SCT model, as noted, failed to account for some findings of extensive RA for episodic memories, which were recently confirmed (Moscovitch et al., 2005; Winocur and Moscovitch, 2011). Consequently, an alternate view is that the hippocampus will always be necessary for retrieving past episodic memories, regardless of the age of the memory. Multiple trace theory suggests that the hippocampus provides retrieval traces or tags to guide memory search for a particular memory, which are always required to recover a memory stored in the neocortex (Moscovitch et al., 2005). Previous studies of RA did not precisely consider that past experiences (i.e., autobiographical memories) inherently consist of both semantic and episodic details. Because previous tests of autobiographical memory did not distinguish between episodic and semantic memories, amnesia appeared to affect recent memories much more than remote memories.

Moreover, if one more carefully looks at semantic memory and episodic memory separately, amnesia tended to spare semantic memory for all life periods except the most recent ones. In contrast, specific details (i.e., sights and emotions) and crucially, the subjective reexperiencing associated with episodic memory, tended to be impoverished following hippocampal damage, regardless of whether the memory was recent or remote (Cipilotti et al., 2001; Viskontas et al., 2000). Parallel patterns are seen in patients with Alzheimer's dementia and semantic dementia: in Alzheimer's dementia, episodic memory for recent and remote events is impaired but semantic memory is relatively preserved, while in the early stages of semantic dementia, remote and recent episodic memories are relatively preserved but semantic memory is impaired (Piolino et al., 2003; Westmacott and Moscovitch, 2003). Finally, fMRI studies of autobiographical retrieval showed that it is qualitative factors related to the subjective reliving of past events (i.e., vividness, perceptual detail) that mediate hippocampal involvement in autobiographical recall (Gilboa et al., 2004; St. Laurent et al., 2009), and not the oldness of the memory per se (Bonnici et al., 2012).

It should be noted that older memories do tend to be less detailed and more schematic. The latter observation led researchers to emphasize that memories are transformed over time and experience, such that as memories become more semantic or schematic, they become independent of the hippocampus and rely instead on extrahippocampal structures (Winocur and Moscovitch, 2011). Insofar as memories retain their perceptual details, they continue to depend on the hippocampus.

Looking Backward to Move Forward: Memory-Related Neural Substrates and Future Thinking

Until recently, human memory research has focused on the study of memory for memory's sake, rather than how memory systems contribute to behavior. Bartlett (1932) noted that the quality of memory is fluid, and susceptible to distortion by cultural factors. In the animal memory literature, it was always assumed that memory conferred great survival value, be it avoiding previous dangerous encounters, or recalling where food was cached (Suddendorf and Corballis, 2007). Similarly, theorists have posited that the ability of humans to reminisce is a special case of the ability to engage in mental time travel, which may go backward, as in autobiographical recall, or forward as in when we try to predict some future scenario. The ability to use past experiences to predict future encounters may confer the benefit of simulating the outcomes of possible actions, without suffering the consequences of actually implementing them if they are undesirable (Boyer, 2008; Buckner and Carroll, 2007; Gilbert and Wilson, 2007; Addis and Schacter, 2012).

Hassabis et al. (2007) found that amnesic people showed deficits in imagining a new experience, such as being at the beach, in that they were not able to describe the event beyond generalities, and had particular deficits in describing spatial details indicative of forming a cohesive representation. Similarly, Addis and colleagues looked at patients with Alzheimer's dementia and found that the hippocampus is needed to imagine future events, just as it is needed to recall past events. Strikingly, the ability to imagine future events seems to mirror autobiographical recall performance in these patients; that is, they can describe the general semantics of events, but cannot describe the details of those events, whether past memories or imagined future scenarios (Addis et al., 2009). Moreover, the ability to construct imagined events also relates to subsequent memory of those events (Romero and Moscovitch, 2012). The propensity to imagine future events that are more semantic (e.g., what do you think the economy will be like in a few years?) is also compromised in amnesic people at the level of details, but not at the level of generalities (Race et al., 2013). Finally, fMRI studies show that the hippocampus is activated during autobiographical recall and future imagining, with specific

subregions of activation for each task (Martin et al., 2011). Other studies have extended these findings to show that the hippocampus aids in simulating possible outcomes with varying levels of value (Benoit et al., 2011), suggesting that the ability to recall past experiences in detail serves purposes other than reminiscence (Pillemer, 2003). One implication of these findings is that the hippocampus may not be best characterized as a memory-specific brain region but rather as a region that is implicated in a host of functions that draw on detailed episodic memories for optimal performance.

Summary

Studying amnesic patients has resulted in several key observations in memory, namely, that memory was not a unitary construct, but had several facets that could operate independently, and rely on separate neural structures. The characterization of amnesia as a disorder only affecting memory was based on the magnitude of the observed effects in LTM, as compared to other cognitive functions. However, recent evidence suggests the characterization of the hippocampus in cognition extends beyond a single memory system (LTM), and may perhaps be better characterized by the nature of the representations it mediates, rather than a discrete memory system (Graham et al., 2010; Henke, 2010). Nevertheless, the notion of distinct memory systems remains useful as a paradigm for characterizing amnesia and other cognitive disorders. As the understanding of brain behavior mappings becomes more precise, the conception of cognitive disorders will also undergo further refinement.
